To make the nice flavor in butter, etc., the cream must be ripened or soured. Nine out of 10 make this the cause of strong, rancid tasting butter; in making the cream too sour. The simplest way to ripen cream is to take it the day before it is to be churned, and very slowly raise the temperature to about 67 degrees in the summer and about 72 in the winter. The way that I raise it is to set the cream pail in a pan of warm water, (not hot water), and keep stirring it, and have the thermometer in it, and watch it very carefully, till I get it where it should be. These temperatures given are the best ones to get the right sour in the cream that will flavor the butter correctly; too high temperatures give it rancid and cheesy flavors and spoil the keeping qualities; too low make bitter flavors. Right here let me state that it is very important that the butter maker have a first-class dairy thermometer. There is not much use trying to make a uniform article without one; this is where many fail in not having one, a good one. After the cream has been heated to the proper temperature, it should be put in a place where that temperature can be kept for six to eight hours, and it should be stirred at times, to make a uniform ripening. When it is noticed that it has just turned, (soured) a little and it has a sharp taste to the sour, it should then be placed in a room where the temperature can drop to churning temperature (around 58 to 60 degrees and let stand for seven or eight hours), say overnight, and then if it has been ripened correctly, it should be thick and glossy. It is safe to state that the ripening part of butter making is where so many fail, and still that is the part that makes the correct flavor to the finished butter. There are ways of ripening bu using starters, but the above method is the easiest to understand.

Proper Temperature

The temperature of the cream when put in the churn should be so that the butter will "come" in about 35 or 45 minutes, which is about 52 to 54 in the summer and 60 to 62 degrees in the winter. If the butter comes sooner than 25 minutes the next churning ought to be cooler, and if the butter takes much over 45 minutes it should be warmer. Butter coming overtime gives better results than if it comes too soon. Barrel or swing churns for home use are the best, as those with clappers, etc. inside are apt to break the grain of the butter. Churning must be stopped when the butter begins to form in granules about the size of cracked corn. Many fail by letting the butter gather in large lumps and thereby incorporating much buttermilk in the butter, which makes a streaky article and causes the butter to get rancid quickly.

After the butter "comes," as above described, the buttermilk should be strained off. It is well to remember that when the cream is put in the churn to strain it also.

After all the butter milk has been drawn off, the temperature of it should be taken, and pure water about the same temperature and the same amount should be used to wash the butter granules. Sometimes if the butter granules are noticed to be rather soft, the temperature of the water can be 5 to 6 degrees lower; if too hard, higher. Strain the water in the churn and very slowly turn the churn over two or three times. Strain off the water and give one more washing. Too many washings take away the nice flavor, so I find that if the granules are as above stated that washings are enough.

MORE CREAM LESS LABOR

Through Using a

NEW DE LAVAL CREAM SEPARATOR

Patriotic duty as well as dollar-and-cents self-interest now demands of every cow owner the saving of every ounce of cream and butter-fat.

Likewise the saving of time that is possible through a cream separator of ample capacity, that is easily turned and always in order.

There was never a summer in the history of the country when both of these considerations were of as great importance to the nation as well as to the individual producer of cream and butter.

Under present circumstances, a modern De Laval Cream Separator will save its cost every few weeks. Every cow owner owes it to himself and his fellow countryment to effect this saving.

This is true whether you have no separator or have an inferior or half-worn-out machine, even if be an old De Laval model.

It is important to remember, too, that if you cannot pay cash for a new De Laval machine, you can buy one on such liberal terms that it will actually pay for itself while you are using it.

Why not see the nearest De Laval agent at once?

If you do not know him, write to the nearest office for new catalogue or any desired information.

Every new De Laval is equipped with a Bell Speed-Indicator.

If it is thought necessary to put coloring to the butter, it should be added to the cream just before it is put into the churn. If the cream has been weighed, and as per directions given with it; but remember not to overcolor, as it gives the butter a cheap look.

If the cream has been weighed, and the amount of butter to be made is known, then about two ounces of salt that has been sifted and moistened a little should be sprinkled over the granules in the churn to each pound of butter, more or less, according to the demands of the customers. Then the churn should be turned over several times until the butter has gotten into large lumps and then left for 15 or 20 minutes for the salt to dissolve. Then the butter can be put on the worker and worked just enough to work in the salt that may be left undissolved, which by this method of salting will be very small. Butter should never be worked with the hands, as it gets a pale, salvy look, and butter ought to be worked only enough to get the salt in and buttermilk that may be washed out, out. But, if the butter is left in granules at the time that it is washed it will be found that there will be very little buttermilk left after washing.

THE BULL MUST HAVE EXERCISE TO BE HEALTHY

The perpetuation of the species is dependent largely upon a robust, vigorous constitution. It is quite true that a weakling may reproduce itself; but always at a disadvantage, as the offspring will invariably be of an inferior order with probably strong tendencies to sterility. This law is evidently a provision of nature to protect animal life from falling below a certain standard; while on the other hand it has made abundant provision for improvement and strengthening of any desirable features.

To overcome any tendency toward degeneration there are some things absolutely necessary; such as proper food, pure air, comfortable physical conditions, sunlight and exercise. All of these are more or less closely related and dependent upon one another in the up-building of all forms of the highest types of animal life such as man and the various domestic animals in which he is most interested. For instance the body cannot be built up properly without good food. The food cannot perform its functions in the body without pure air, not only for respiration but also for the oxidation and purifying of the blood. The sun is the source of plant life, and these form the food of animals. Nor can any of the organs of the body perform their proper functions without exercise to break down and expel the unused portions of food and develop and strengthen that required in the sustaining and up-building process.

While an animal can live for some time and neglect to take a sufficient amount of exercise, sooner or later, nature's laws will demand a readjustment and that a proper balance between this and the other important elements of life be restored or a physical breakdown cannot be averted.

Aside from the observance of these principles in man there is no class of animals that will be more largely benefitted by a proper amount of daily exercise or injured by the neglect to observe this fundamental law of good health, than the herd sire.

On account of the vicious disposition of many bulls and the liability of any of them to become dangerous at any moment, without warning, they are very frequently kept in close confinement and do not get nearly all the exercise that they should have, in order to maintain normal health; particularly after a herd sire has reached maturity and shows signs of becoming vicious. This often occurs, too, just at a time when the animal has proven himself to be a valuable sire. Hence it is most important that he should be continued in the herd. With the object in view of maintaining the usefulness of a sire in the herd let us look at some of the ways that he may be given a sufficient amount of exercise to keep him in normal health.

Right here let it be understood that what is said in this connection does not apply to any extreme case. There is now and again a bull that is not safe to keep on a farm at all unless very exceptional precautions are taken to place him beyond the possibility of endangering the lives of attendants or others who may have business about the place. Unless an animal of the kind is very valuable as a breeder of producing daughters it will be better to use him for food; but if thought otherwise, no doubt if sufficient expense is spent for protection from danger ,he can be made safe, but this fact should be made secure.

For ordinary animals a good box stall is sufficient. This can be made so strong that anything less than the most vicious can be made secure at a moderate expense and at more cost even these can be controlled with safety. The horns should be taken off a bull with a very bad temper. Relieved of these offensive weapons he will be much less inclined to be destructive, and even if he were he could not be, to the same extent. A box stall for this purpose can be made of good posts set deeply into the ground, into cement or shallower into cement and fastened to the joists if in the basement of a barn. On these should be bolted sound plank on the inside of the post. These with a window properly guarded with iron rods and a very strong door with bolted hinges properly keyed so that they cannot be thrown off and in addition to bars, chained when shut will secure a bull in absolute safety.

Where permanent bull pen is made outside the main barn, a comparatively cheap and permanent one can be made of cement. This should be made large enough for the animal to exercise freely and so that when breeding a cow there should be plenty of room. Sixteen by twenty feet with a feeding stall at one end into which he could be coaxed or driven when desired with a strong door in the rear which could be closed to keep him in for cleaning out the pen or attaching a staff to his nose ring would be a fair size. The stall door could swing around in front of the pen door making an entry or back flat against the side of stall and fastened there when not in use.

Again steel pens may be purchased from manufacturers ready to be installed. These with cement connections make very good enclosures, but are usually too small and come pretty expensive when made large. For an inside pen they are neat and sanitary, however, and where other means of giving further exercise is provided for are a satisfactory enclosure.

In addition to the box-stalls or pens the tread-power has been used to some extent as a means to this end, and occasionally furnishes a double end by supplying light power for such purposes as pulping roots, pumping water and other light work. There are many discarded machines about the country that could be used for this purpose, the cost of which would be normal but which, if used for no other purpose could be utilized to advantage for this purpose.

Another plan is to use two strong and high posts to which is attached a strong wire near the top, running from one to the other. A ring is placed on this wire to wich is attached a lead chain running from the bull's nose ring. The animal can then walk up and down the whole length of the wire, the ring sliding along on it and controlling his movements. When this method is used care should be taken not to have the lead chain to long so that the bull will get his feet over it. If more convenient the wire may be attached to two buildings of suitable distance apart.

It is often advisable to select hard ground or a gravelly road to exercise the bull on, in order to wear his hoofs down to proper levels.

Almost any capable farmer or stockman can manage to fix up some sort of place in which to give the bull his needed exercise if he sets about the accomplishment of this purpose; but the trouble is that enough importance is not attached to the subject, or at other times it is a matter easily left over to a more "convenient day" and so goes by default altogether.

Until farmers fully realize that strong constitutioned animals cannot be bred from bulls weakened by want of exercise, this important matter will continue to be neglected.—O. V. J.

SELECTING CATTLE FOR GRADED HERD

When making selection for exhibiting graded groups of cattle for competition, many good breeders and successful exhibitors of single cattle fail to put up a good show with their groups. They do not put their cattle through the fanning mill. When an exhibitor is preparing his grain entry, he subjects it to a severe testing through the fanning mill, or when he is to exhibit roots or apples, he makes very careful selection, and when he has found an ideal sample he tries to choose all the other similar so that a uniform shape and idea of type prevails. There is no other way of catching the eye of the judge, or of showing the produce at its best.

The fanning mill for the cattle is the rigid selection of conformation, color, and type. Have all the cattle in the group of the same type, even though you have to sacrifice the presence of one of your prizetakers. Practice at home with your herd and pick out the group of five or six necessary for the entry. Take all those to the show ground and rigidly keep to them when showing for a group. They may not be very successful as individuals in the prize list, but they will have all the chance you can give them in gaining the coveted places with the group. Do not place all your first prize animals in the group on the assumption that if they were first prize winners in the single competition that they will be unbeaten in the graded group. Grading for groups is a different matter, and only few exhibitors seem to practice the art.

Where groups are shown by expert graders the great diversity of types can be noted and compared to full advantage to the breed type. Where many types of single individuals are mixed together in classes for single animals this variation of breed type is apt to get lost. Grading is of vital importance to the breed, and until it is fully understood by all exhibitors, much of their useful work will be lost. There is no finer sight to be seen in any exhibit of live stock than this of group showing, where each are chosen after the distinctive type of some family or strain, of some outstanding prepotent sire or dam, and certainly no other way whereby breeders' animals are so well shown to advantage. Grading has its value in breeding as well as in showing, and the graded group in the showing is no fanciful exhibit; it is there to fulfil an end; is an object lesson to the breeder. Live stock breeding is valueless to the individual breeder or to the breed, if grading at home is neglected.—O. V. J.

This New Farm Boot

CHROMOIL TANNED

BY

Palmer-McLellan

FOR SUMMER WEAR

POSTPAID TO YOU FOR

$4.50

The wonderful chromoil leather in these boots is a big improvement on the best ordinary "Oil-Tan." It is waterproof not only on the surface but all the way through. It does not dry out nor crack from heat, nor stiffen up quickly from frost. It retains through everything the soft suppleness that makes it so comfortable.

The shape, too, is n w and better, combining the easy comfort of the Indian moccasin with the permanent form of a regular boot. This is ensured by building it on a last, and giving it a solid extra long counter in the heel. It's a boot that will stand up to the hardest kind of service, in any weather, and outwear any other working boot you have ever tried.

At the same time, it is light in weight and easy on the feet, and remarkable value for the price.

If your dealer cannot supply you with these new Palmer-McLellan Chromoil Tanned Farm Boots, mail us the price and we will ship you a pair postpaid.

BREEDERS' DIRECTORY FOR SHEEP AND SWINE

The past year has seen a marked increase in the demand for sheep and swine, both pure bred and commercial, among the farmers for breeding purposes. This demand is, of course, due in part to the greatly increased price of lamb, mutton and wool and in pork and its products. Further, farmers in the Maritime Provinces are realizing that there are considerable areas of waste land that could be utilized very profitably through sheep.

As this demand has grown very rapidly much difficulty has been experienced by intending purchasers, in their efforts to locate breeders of sheep and swine from whom reasonable numbers of breeding animals could be obtained. Already numerous inquiries are being made by men who are desirous of purchasing, as to where animals can be located and purchased for fall delivery.

In this connection, so far as sheep are concerned, breeders would be well advised to retain their best ewe lambs for sale for breeding purposes, since all indications point to a continued demand for breediny females and the conserving of ewe lambs is the only ultimate source for supplyinp that demand and permanently increasing our sheep population.

With this in view, and in order to facilitate and direct breeders, G. Erle O'Brien, Representative for Sheep and Swine Husbandry in the Maritime Provinces, under direction of the Live Stock Branch, Dominion Department of Agriculture, has prepared a breeders' directory for pure bred and commercial sheep and for pure bred and commercial swine in each of the Maritime Provinces, Nova Scotia, New Brunswick and Prince Edward Island. This directory contains the name of the breeder, his address, the breed of sheep offered for sale, and the number of animals for sale annually.

This directory of breeders of sheep and swine can be obtained by making application to the Live Stock Branch, Dominion Department of Agriculture, Ottawa.

GRUB IN THE HEAD

Will you please tell me, through the Sheep Column of your paper, the best treatment for sheep afflicted with grub in the head?

Ans.: Thomas Shaw, a noted authority on sheep, says: "Treatment for grub in the head is practically out of the question," while an English writer says: "Treatment—which is not very satisfactory—consists in the injection into the nasal cavities of some agent destructive to the parasite. This may be done as follows: Procure an elastic bulb syringe with a small nozzle about 6 in. long, and practice with it a few times until able to expel about a teaspoonful at a time. Fill the syringe with olive oil and turpentine in equal quantities, pass the nozzle of the syringe up the nostril, and by a sharp movement inject about a tea-

spoonful; withdraw the syringe, and in a few moments serve the other nostril in the same manner. Prevention.—A means of prevention is to apply to the noses of the sheep with a brush a mixture of equal parts of tar and whale or fish oil once every two or three days during the hot summer weather. Or the following ointment may be used in the same way: Beeswax, 1 lb.; linseed oil, 1 pint; melt together with 2 oz. common resin, and, as this cools, stir in 4 oz. of carbolic acid."

Another Treatment

As soon as first noticed, the grub can be killed and absorbed away by giving spirits of turpentine, ¼ oz. or 1 tablespoonful; raw linseed oil, ½ teacupful. Mix and give as a drench every second or third day for a week or so. This will kill the grub, which will gradually absorb away itself, and the sheep will soon be all right. During treatment, keep the sheep in a small field where it cannot hurt itself; catch it every day and feel around the top of the head for a soft spot in the bone over the brain by pressing hard on it, and when you find it, take a sharp knife and cut the skin off the soft spot about the size of a 25-cent piece, and then cut the diseased bone, being careful not to touch the brain. As soon as you have cut around it, raise the piece of soft bone out and leave it out. This soft piece of bone, being ever where the grub is, will at once give the sheep relief, for the grub will bulge up in the hole and take the pressure off the brain. Do not attempt to remove the grub, for nature will remove it in a few days itself. The only thing to be done after the bone is cut is to keep the sheep in a cool place where flies will not bother it and cause maggots. If they should, wash it out clean with lukewarm water and soap, then apply the white lotion with a few drops of carbolic acid in it once or twice a day and it will be all right. The hole in the bone will soon heal over. Providing you should lose a sheep with this disease, bury it deep so the dogs will not get it and carry it to other sheep. Never, in any case, pour spirits of turpentine in the nostrils, for it will do not good, is cruel, and sometimes kills the sheep itself. Always give the turpentine as above mentioned.

VALUE OF MANURE FROM TWENTY-FOUR STEERS

The manure from twenty-four steers averaging in weight close to 1000 pounds each, and running loose in two box stalls at the Experimental Station, Kentville, N. S., covering a period of 120 days, or four months, weighed 112 tons, 640 pounds. The average for each day was 1872 pounds, or 78 pounds per steer. Straw bedding amounting to 10 pounds per steer per day, was used and all liquids as well as the solids were saved.

Chemists tell us that this fresh manure from fairly wel-fed steers, contains in each ton 7¾ pounds nitrogen, 3½ pounds of phosphoric acid and 9 pounds of potash. When buying commercial fertilizer we pay 25 cents per pound for nitrogen, and 7 to 8 cents for phosphoric acid. Potash cannot be bought at any price, but in order to get at a fair valuation for the manure, we should allow at least 5 cents per pound, the price of potash before the war.

A ton of the above manure at these prices would, therefore, have a value of $2.63.

At the valuation of $2.63 per ton, 112 tons, 640 pounds would be worth $295.40, or $12.31 per steer, a little over $3.00 per steer per month. Considering that potash will each year become a greater factor in economical agricultural production, the value is even greater than that given above.

Nothing has been allowed in the above calculation for the value of the humus. It is estimated that the humus value of manure is 50 to 100 per cent. of the value of the chemical ingredients, depending upon the soil on which the manure is used and the manner of application.

It is a well-known fact that half of the total value of the excrement from live stock is in the urine. If the liquid part is allowed to drain away through holes in the stable floor, or otherwise, over one half of the value of the manure will be lost, therefore, every effort should be made to conserve all the excrement voided by animals.

The water retained after twenty-four hours by 100 pounds of material used for absorbents in the stable is estimated to be as follows:—

Wheat straw, 220 pounds; Well dried peat, 600 pounds; Dry sawdust, 435 pounds; Dried leaves, 162 pounds.

DIP FOR SHEEP TICK

My sheep have a heavy fleece badly infested with ticks. Of course they cannot be clipped until warm weather. What can I do to rid them of these ticks?—(W. F.

There is only one sure way to get rid of sheep tick, and that is to dip. If you have a warm stable and can give the sheep shelter choose a moderately warm day and shear the sheep. If in your judgment in your locality weather conditions will likely make it very unwise to shear at this time you might try to dip the sheep with fleece on, but this is very unsatisfactory. In dipping use some well-recommended coal tar preparation and be careful in handling the ewes. Shear the sheep as soon as possible and then dip.

KEEP YOUNG CALVES SEPARATE

According to the Wisconsin agricultural college it is a good practice to keep the calves separated and penned in groups according to their ages. They can be fastened in stanchions when milk is fed and grain can be supplied them immediately after they drink. Feeding the grain at this time and keeping them locked in stanchions until the grain is eaten helps to overcome the habit of sucking. Calves that continue to suck one another after being turned loose should be separated or some other means taken to prevent the practice.

Men who know engines buy

THE ALPHA

Cheap horses don't pay and neither does a cheap gas engine.

You can buy an old "plug" for little or nothing, but you can't get the work out of him that you can out of a big, healthy farm horse. That's the reason you can buy him cheap.

It's just the same with a gas engine.

You can buy a cheaply made, poorly designed engine for less than the price of an Alpha, but you will find that the expense for constant repairs and the annoyance of having it get out of order just when you want to use it, make it a pretty expensive piece of equipment to have around.

There are farmers all over Canada who, after trying to save money by buying cheap engines, have discarded them and bought Alphas and been glad they did ever since.

You will save yourself needless expense and annoyance if you profit by their experience.

Ask for catalogue, prices and complete information. Made in eleven sizes, 2 to 28 H. P. Each furnished in stationary, semi-portable or portable style, and with hopper or tank cooled cylinder.

TIME OF BREEDING HEIFERS

Numerous factors are responsible for complete and early development of breeding heifers. If properly fed and housed, nothing exerts greater influence upon the final size of the animals than time of breeding. Early breeding is quite often practiced to the disadvantage and detriment of the future herd. The most desirable type of milch cows has a large body capable of consuming and digesting large quantities of feed. Early breeding prevents the desired growth and is not warranted under average conditions. The age of breeding should be largely governed by the size of the breeding heifers rather than their age.

FARMERS

SHIP YOUR WOOL DIRECT TO US

The Highest Prices Ever Paid for Wool are Now Being Paid By Us

Mr. Farmer, you can get more money for your wool by sending it direct to us.
In all probability it will come to us anyway at some time, no matter to whom you sell it.
For over thirty years we have been one of the largest buyers of wool in Canada. We could not continue in business for this length of time if we had not treated our customers fairly and pay top prices. We send your money the same day as wool is received, only deducting freight or express charges.

We are now paying for wool as follows:
Unwashed fleece—fine..53c to 54c per lb.
Unwashed fleece—coarse 51c to 52c per lb.
Washed fleece—fine....67c to 68c per lb.
Washed fleece—coarse..65c to 67c per lb.

Ship to-day or write us telling how much wool you have, if washed or unwashed, and breed of sheep clipped from. We will then quote you a straight price and send you shipping tags with full instructions.

John Hallam Limited TORONTO

THE HORSE

INFLUENCE OF THE SIRE

Any good breeder of live stock will tell you that the sire is half the flock. By that he means that half the breeding, which results in the immediate offspring, is by way of the sire. There is no other means of building up a herd or flock which will bring quicker success than by selecting a good male. But the question of what constitutes a good male is quite another phase and is not answered in one sentence. If breeders could pick out sires or males that could transmit the qualities desired, the improvement of the herd or flock would be a simple matter.

There has been a great deal written on the selection of the male, and much of it is of prime importance, but after all has been said and done the conclusion is that there is but one absolute test—the actual production of daughters that meet the requirements. This, of course, is especially true for dairy cattle, since the production of milk is not so closely allied with form as is the production of meat in beef cattle or strength in draft horses. However, with the latter, the best of stallions sometimes fail to produce desirable typed off-spring.

This method of testing is expensive and for the dairyman loses the use of the bull during the three years or more of waiting and this is often the most valuable part of the animal's life. On the other hand many good herds have been spoiled for several years, due to the selection of an unworthy sire and this expense is far greater than the first.

It is a common practice among the dairymen of the eastern states to use comparatively young bulls in their herds for two years only, and then sell them and depend upon another young bull which they have, in the meantime, raised for the head of the herd. This practice seems at first hand to be the only practical method of procedure, because after the age of three years the bull has attained his full growth, is a heavy feeder and is hard to manage in some cases. If continued longer in the herd inbreeding would result. The question arises as to what is the proper way to avoid this trouble. The smaller breeders cannot afford to maintain two separate herd sires, hence they have not kept a bull in service long enough to prove his value.

When the dairyman purchases a calf to raise as the head of his flock and intends to keep him only two years he is very likely to be influenced to accept a cheaper individual than he would if he knew he could hold him longer. He will secure a bull calf whose ancestors have been as heavy producers as he feels he can pay for.

As a means of removing this danger as far as possible there are several methods of procedure. The first and probably more influential method with the largest number of dairymen is to purchase an exceptional animal from a breeder of known reputation. Then while he is in service in the herd to locate another breeder who is using a similar aged bull of much the same family lines and make arrangements to exchange with him. This may be a complete or qualified exchange as the breeders see fit. An understanding as to the recalling of the former sire at the end of two years is usually made.

Some breeders do not approve of this plan because of risks involved, the extra amount of feed required to maintain an animal of that age, and an inborn feeling that the other fellow will not play square. These breeders do not stop to consider that the extra amount of capital which they are investing in a new sire every second year is a more serious loss in their business than the extra feed necessary. Harmony among the better class of breeders is also being rapidly established.

The second and probably more to be desired method is to join a co-operative bull association. In this way the capital is lessened for each member and bulls of proved merit and very exceptional breeding may be brought into the community. The improvement of the stock in a community means as much or more money to the wide-awake breeder as it would if he had had the capital in the beginning to improve his own herd.

Records of cattle herds maintained by the various stations throughout the country have forcibly brought to our attention the necessity of being more careful as to the real value of our sires. The result of the Missouri station which showed that out of 11 sires used in their two herds, three were decidedly inferior, two were practically neutral and six were superior in their transmitting powers, is a positive proof that there is a call for more careful and constructive breeding.

As for the sires in other branches of live stock the same principles in modified degrees are practical. Stallions are kept in a community for a sufficient length of time to show what they will produce, and breeders are always skeptical about breeding all their mares to an unproved stallion. In sheep and swine breeding interchanges of males among breeders is a common and usually a commendable practice, except where a large flock or herd is maintained and several males are necessary.

FILLY'S FOOT TROUBLE.

We have a three-year-old filly, about 16.1 hands, which at the beginning of the winter took gravel in her off fore foot. She became lame, and I had it cut out by the smith. Her hoof is rather hot, and puss gathers in it all the while. The hole runs under her shoe to the front of her hoof, and then runs down into the live. It is cleaned out regularly and turpentine is applied to it. She has had a leather under her hoof for a considerable time now, but we have left that off. She is at work every day, as she is just as lame when at rest. Can treatment of her be done without rest? We have not had any stone or gravel out of the hole.—F. G. J.

Answer:—These cases are very troublesome, and try the patience of both owner and attendant. They sometimes go on for months and months, and suddenly heal up in a few days. As the smith has made a good opening it ought to be fairly easy to dress. Discontinue using the turpentine and apply pledgets of tow which have been soaked in either a 5 per cent. solution of chloride of zinc or peroxide of hydrogen 10 volumes. In these cases there is generally either a foreign body or a piece of dead tissue, which keeps causing inflammation and suppuration of the parts. See that after wet days or working in the mud that the place is well washed out and disinfected with the peroxide, as small pieces of dire or grit irritate the exposed sensitive tissue. Keep the bedding and stable floor as clean and dry as possible.

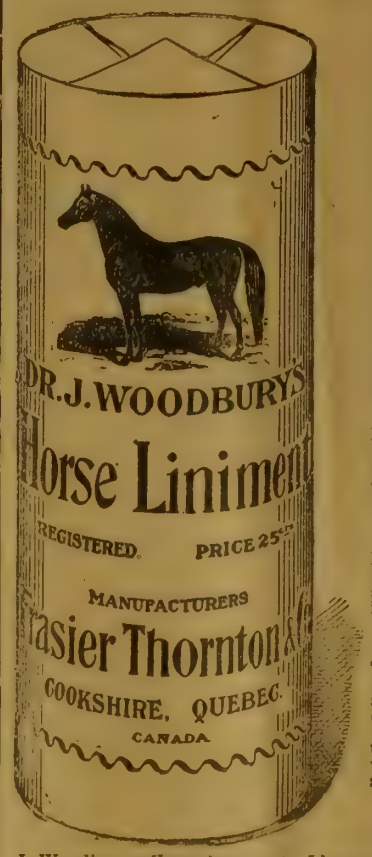
HORSE WITH CRACKED HEELS

Would you kindly let me know if there is a cure for cracked heels or knees? I have a half-bred horse that has them in both forelegs above the heels on the pasterns, and there is dried skin or hack between the openings, which stops them from healing. Would a blister or anything likewise clean the hack off so that they would heal up?—M. D. H.

Answer:—The great difficulty sometimes experienced in healing cracked heels lies in the fact that the wound does not get rest, and the crack continually is opened by the bending of the foot, and also, that the wet and dirt often get into them. So the first thing, if possible, is to rest the horse. Cleanse the crack by using a warm bread poultice, then apply the following lotion by means of cottonwool pledgets soaked in the lotion, and put in the hollow of the heels, a tight bandage put over all, and up above the fetlock:—Liq. zinc chlorid., 2dr.; liq. alum. chlorid., 1oz.; glycerine, 2oz.; water to half pint. As soon as the crack is dry and nearly healed, use the following ointment, which should be rubbed in every night:—Ung. hyd. ox. rub., ½oz.; ung. zinci, 1½ oz.; liq. picis

Dr. J. Woodbury's Horse Liniment

THE INFALLIBLE REMEDY



For the removal of Splints, Bog Spavins, enlargements of any and every description it has no equal. Given internally, it will promptly relieve and remove any and every character of Cough Enlargements of the Glands, Affections of the Kidneys. For distemper, strangles, and colic it is infallibly the remedy All horses that are stabled should have an application of Dr. J. Woodbury's Horse Liniment to the hoofs of the forefeet to prevent their becoming feverish, dry, brittle, hard, contracted or otherwise injured Insist on having Dr. J. Woodbury's Horse Liniment. We warrant it to effect that for which it is recommended when used according to directions. Its beneficial effects are so prompt and decided that it has excited the admiration of the leading horsemen of the Dominion and secured their highest confidence.

Bear River, N. S.

Dear Sirs:—We do not hesitate in recommending your Dr. Woodbury's Horse Liniment. We have used it in the woods for coughs, colds, distemper and cuts and would say that no lumberman should be without it.

Yours truly, Clarke Bros.

Hubbard's Cove, N. S.

Dear Sirs:—I have used Dr J. Woodbury's Horse Liniment in my stable for years and consider it the best liniment on the market for both internal and external use.

Yours truly, C. C. McLean.

Truro, N. S.

This is to certify that I have used Dr. J. Woodbury's Horse Liniment with the very best results for colds, coughs, distemper and all lung deseases. It is the best to give horses in the spring to keep them in condition. It purifies the blood, cleanses the lungs from impurities which may exist and gives the system healthy action.

Newton Lee, Owner "All Right" 5817.

Elmsdale, N. S.

Dear Sirs:—Kindly send me 6 dozen bottles Dr. J. Woodbury s Horse Liniment. I have not a bottle in the store and it is the only kind my customers will take. Yours truly, Elmsdale Mercantile Co.

Elmsdale, N. S. Dear Sirs:—I cured my horse with Dr. J. Woodbury's Horse Liniment. It was a bad case of distemper. I always recommend this liniment to my friends as the best for all diseases of the horse. Yours truly, H. R. Whitehead.

Dear Sirs:—One of my horses had a bad cough and I made a complete cure with three bottles of Dr. J. Woodbury's Horse Liniment. The cough was of twelve months standing. In my large experience with horses I consider this liniment to be the best made for all diseases in the horse, I recommend it to my friends. E. J. Anderson, Truro, N. S.

WORKING HEAVY HORSES

For the guidance of drivers that they may get more and better work from their horses, the Boston work horse parade association has made these suggestions. They are as applicable to farm work as to city trucking.

Start at a walk, and let your horse work very easily for the first half hour. A heavy draft horse should never be driven faster than a walk, with or without a load.

Look to your harness. Avoid these faults especially: Bridle too long or too short; blinders pressing on the eye or flapping; Throat latch too tight; collar too tight or too loose; shaft girt too loose; traces too long; breeching too low down or too loose; inside reins too long, in the case of pairs.

Drive your horse all the time. Feel his mouth gently. Never jerk the reins. Take the horse out of the shafts as much as possible, and if you drive a pair or four, unfasten the outside traces while the horses are standing; they will rest better that way.

Teach your horses to go into the collar gradually. When a load is to be started, speak to the horses and take a firm hold of the reins so that they will arch their necks, keep their legs under them, and step on their toes. A loose rein means sprawling and slipping, often with one horse ahead of the other.

Water your horse as often as possible. Water in moderate quanities will not hurt him, so long as he keeps moving.

Blanket your horse carefully when he stands, especially if he is at all hot. Repeated slight chills stiffen and age a horse before his time.

Bring your horse in cool and breathing easily. If he comes in hot, he will sweat in the stable, and the sudden stoppage of hard work is bad for his feet.

In hot weather or in drawing heavy loads, watch your horse's breathing. If he breathes hard, or short and quick, it is time to stop.

Remember that the horse is the most nervous of all animals, and that little things annoy and irritate him. Remember that he will be contented or miserable accordingly as you treat him.

BED THE HORSES

On many farms large straw stacks are allowed to rot in the field while the horses go unbedded. Some farms also have stacks of threshed clover and damaged hay which could be very profitably utilized as bedding. The liquid part of manure is really the most valuable part and where plenty of bedding is used this is absorbed and saved; if no bedding is used most of it is leached away. The manure is also more easily handled and contains more humus.

In cold weather a horse suffers very much if not bedded. Plank or cement floors are very cold and the horses lying upon them are liable to chill. More feed is required to keep such a horse warm. Even in warm weather horses should be bedded, as they cannot get proper rest when lying upon a hard floor. The horse's coat is much easier kept clean and glossy where bedding is used. Horses, even when very tired, will stand most of the time rather than lie down upon cold and uncomfortable beds.

Leaves make most excellent bedding material and act very well as an absorbent. Many people rake up the leaves in the spring and burn them. Why not rake them up in the fall and use them for bedding through the winter? Many allow their stacks to rot in the field and then spread them upon the land. The value of the fertilizer would be many times increased if the owner would but work it up with the manure.—Carlos J. Griffing, Delaware Co., O.

"I could not have done without it this Summer, as help is so scarce"

Here is the experience of one of the scores of dairy farmers for whom the

EMPIRE Mechanical Milker

is taking the place of the farm help they can no longer get, and enabling them to keep their herds together and take advantage of the prevailing high prices.

R. R. No. 3, INGERSOLL, ONT.

Gentlemen:—

I have used one of your "Empire Milkers" since early last April, on from 40 to 45 cows continually, and can find no injurious effects on the cows. They seemed to like it from the first time, and I think gave rather more milk than with the best hand milking. Easy cows seemed less inclined to leak, and hard ones gradually became easier.

I have sent the milk a number of years to the Borden Condenser Company, and have had no complaints. I have just followed the instructions for keeping it clean.

I could not not have done without it this summer, as help is so scarce. I may say further that I have been milking cows for over 50 years, and have been in the milk business nearly that length of time. I have had no previous experience with milking machines, but have had very little trouble or expense for repairs. I have used it on heifers never milked before, with perfect satisfaction, no matter how small their teats were.

The Milker has been of more practical value to me than I ever expected.

WILLIAM COLYER.

We will be glad to send you Booklets showing exactly how the Empire Mechanical Milker works, and telling the experience which dozens of prominent dairy farmers have had with it. Address Dept. L

The Empire Cream Separator Co. of Canada, Limited,

58 MONTREAL. TORONTO. WINNIPEG.

WORK THE HORSE EASY AT START

When the soft horse is started at heavy work, the shoulders should be given a good deal of care. The horse will need frequent breathing spells and at these times life the collar so as to give the shoulder a chance to cool and to dry. When it becomes moist from sweat, it will become sore much quicker than if dry. The collar should be kept smooth, if any incrustations form on it, scrape them off. Care should be used in making sure that the horse has the collar that is fitted to its shoulders. A misfit collar is apt to lead to shoulder trouble. When starting the horse at hard work, watch its shoulders and neck, too, carefully.

Even if the farm tractors do come, good horses will still be needed. And Europe is already short of horses, and the United States will be equally short if the war goes on.

It is estimated that an acre of beans will produce as much food material for human consumption as five to fifteen acres of pasture.

Two Cases of Eczema and How They Were Cured

Further Proof That Dr. Chase's Ointment is a Positive Cure for Chronic Eczema.

If you read these letters you will find that Dr. Chase's Ointment is not to be classed among ordinary salves and ointments.

By actually curing itching, stinging eczema in many thousands of cases it has stood the most severe test to which any ointment can be put.

Mr. J. Brice, Temperance road, Parry Sound, Ont., writes: "Just a line to praise Dr. Chase's Ointment for what it has done for my wife. She has been suffering with eczema in her head for two years, and has spent no end of money with doctors and for ointments, which did her no good. She had about given up hope of ever being cured, when someone told her to try Dr. Chase's Ointment. By the use of this Ointment the trouble has left her entirely, so we have unbounded faith in it. I have told several people about the Ointment."

Mrs. W. G. Dowden, Greenspond, Bonavista Bay, Nfld., writes: "I suffered with eczema on my hands, and for eighteen months was so bad that I could not use a needle to sew or do anything. I could scarcely dress myself. Though I had lots of salves from doctors, I could never get much benefit from them. I sent for a sample of Dr. Chase's Ointment, and found it very [illegible] in action. It was not long before my hands began to heal, and four 60c boxes made them well. I cannot praise Dr. Chase's Ointment too highly and frequently give some to others to get them using it, for I know that it will cure."

In the home Dr. Chase's Ointment is of almost daily usefulness, for by relieving chafing and irritation of the skin it prevents eczema and similar itching skin diseases. Applied to all cuts and wounds, it prevents blood poisoning and heals the skin. Dr. Chase's Ointment, 60 cents a box, all dealers, or Edmanson, Bates & Co., Ltd., Toronto.

POULTRY.

CONSERVE TO PRODUCE AND PRODUCE TO CONSERVE

Let us lay out a program, rather an extended one, for the CONSERVATION of poultry this summer and fall, and for increased PRODUCTION next breeding season.

1. Keep the chicks growing. If you are so situated let the pullets have ample liberty, they will pick up a good part of their food, grass, bugs, weed seeds, etc. If not so situated feed an abundance of green food, you can get it if your eyes are open. Dandelions, a weed, cannot be beaten, used either raw or cooked. Keep the pullets busy, they are the mainstay of next season's egg and breeding operations.

2. Select the cockerels early that you desire to keep, treat them well. Push those you do not want, and either sell or eat them, or can their flesh for next winter's consumption in the home. This will run us through June, July and August—as far as the young stock goes.

3. It is recommended that an average flock should consist of 50% pullets and 50% of yearlings. This argument, sound on the whole, is subject to modification under present circumstances. It has paid us and others to keep over two-year-old hens on an intelligent selection. We have in mind now one flock, at least, that is giving a 75% production of eggs on a very moderate ration, and no individual in the flock is under two years old. These hens' eggs are large and well shelled, too. Therefore, do not kill off too fast. Keep over for next season 25% of the two-year-olds, all the one-year-olds and all the healthy, well grown pullets. Force part for early egg production. When done laying sell or eat the hens if thought best. We figure that adoption of this plan would give a natural increase of breeding stock for 1918 season of at least 50%. And we will need them all. Briefly, do not kill any females that you have accommodation and feed for, and that can be reasonably expected to profitably produce.

5. "Swat the rooster," the fellow you do not need, and "do it now." He produces no eggs, he may spoil those that are produced. His feed is needed, conserve it by eating him.

5. Save your surplus eggs by packing them in water glass. It is unlikely that eggs will be any cheaper next winter than they were last winter. Why buy veal and lamb that should not be on the market at all, and sell eggs? Eat them or save them. This applies to the small producer only. The poultry farmer must sell if community cold storage is not available. He should join an egg circle or help promote one if none in his district.

6. If you have too many head to comfortably winter—we are now into October, the harvest month—don't kill them. Get that neighbourly feeling, Mr. Smih, Mr. Jones, Mr. Brown, on your street or route can be induced to keep poultry. He may have an old shed or barn that can be turned to good use. Go shares with him even, if he is doubtful. Production—conservation is true patriotism. Food is as necessary as bullets. "Do your bit" by getting your neighbors and friends interested in poultry.

7. We are now well into winter. November and December eggs are the most profitable of the year, if you can get them. Aim to do so. If the flock is divided into layers and breeders, force the former, keep the latter fit and eager for their feed. In fact this is wise in all cases.

8. Begin hatching early from birds mated in November. Aim for 1918 to double production, sell early to give the remainder an opportunity to grow. Cultivate a local trade, use none but Standard-breds. Help form a club or association if none near you. If one already in existence, join it for mutual help. Get that "other fellow" in too. He wants help as much as you do. He won't be less interested than you are, less eager to help fill the world's markets. A few dozen eggs may seem small but they may save the life of one who has fought for you, and is paying the cost. Nothing is too small. We cannot sit down in this blessed Canada of ours to full tables and see our kin and Allies suffer and starve. Let us produce more than we need. The world is ready for the surplus. It will be just as ready in 1918.

"OLD ROOSTER WEEK"

Truro, Nova Scotia.

Editor The Maritime Farmer:

The great importance of conserving the egg production of the Province is now considered a duty which should not be neglected. The prices of eggs have ruled higher to this date than in any year in the past and it is now a fore-gone conclusion that high prices will prevail during the fall and winter. It is also a fact that the production has not been as large this past season as in recent former years. Eggs may be very scarce and at any price, difficult to obtain if great care is not taken to keep the fowls producing and to keep the eggs produced in such a manner that in storage they will give the best results, and little or no loss result.

One cause of much loss in eggs during the warm weather is the male bird in the flock, after the breeding season is over. Eggs which have been fertilized are inferior for storage, and in warm weather are a constant source of loss, due to the fact that germination will begin in such fertile eggs at any temperature above 65° F. On the other hand, an infertile egg will not become decomposed, but may become stale. It rarely becomes unfit for food. It will stand storing much better and is to be preferred at all times to the egg from a mated pen of fowls. Farmers do not pay any attention to removing the male bird from the pen at the close of the breeding season, and therefore the average of the eggs produced on the farms is of a doubtful quality.

The writer would suggest that the last week in June be named "Old Rooster Week" and for all farmers, as a patriotic duty, kill off the cock birds in the pens and thus help to conserve the egg production in our province and the Empire.

Yours truly,
J. P. LANDRY.

A POULTRY ORDER FROM JAPAN

Mrs. Sarah E. Moses Smith, Woodward's Cove, Grand Manan, N. B., who advertises in the columns of The Maritime Farmer, recently received an order for a pen of Blue Orpingtons from Japan. The letter ordering the birds read as follows:—

Yokohama, 27th March, 1917.

Mr. Sarah Smith,
North Head, N. B., Canada.

Dear Sir:—

I learn from a Farmer Journal that you are raising excellent Blue Orpington.

I would like to have a male and five females of Blue Orpington for breeding purposes. These must be of the following description.

(1) All the birds must be six months up, but not over 18 months.

(2) Birds must be standard type, shape, color and comb, and of pure brood.

(3) The cock bird must have strong compulate power and the hen must be most heavy layer in your firm, having all the same color.

In regard to the price of the birds, I shall send you sixty dollars for American money, delivered free your forwarding agency. I am very gled if you will kindly send me untouched photograph of the birds, which you will ship for $60.

When I had imported Butter Cups last year from America, they had delivered free by Wells Fargo Express Co.

I hope you will ask the Wells Fargo Co., if they will allow me to have them delivered free or not. If he will not allow me free delivery, please quote me your price, including all the charges to Yokohama.

Upon receipt of your favourable reply, I shall soon give you above order.

The summer is the most dangerous season for shipping, so I hope to have them before summer.

Kindly write me as fast as you can, and if you can, write the name of the ship on which the birds come on.

Soliciting your most early reply,
Yours faithfully,
K. HIROOKA.

Address:
K. Hirooka,
Kotobukicho, 1 Chome,
Yokohama,
Japan.

SAVING EGG LOSSES

The Federal government estimates that 17 per cent. of the eggs produced in the United States are wasted because of improper methods of production and handling of this product. It is probable that the fault lies almost entirely with the producers and small dealer and that this could be very easily remedied if the farmer would adopt proper methods of producing and handling this product. The 17 per cent. loss of market eggs mentioned above is itemized by the Federal government as follows:—

Dirty eggs	2 per cent
Breakage	2 per cent
Chicks developed (fertile eggs)	5 per cent
Shrunken or held	5 per cent
Rotten	2.5 per cent
Moldy, bad flavor	.5 per cent
Total	17 per cent

The farmer sustains the greater part of this loss and the middleman and consumers suffer only a small part of it. Again, this 17 per cent. only includes that part of the product which is absolutely lost or is in an unfit condition for food. There is also a large percentage of eggs believed by the farmer to grade as the best market eggs, which, upon reaching the consumer, are graded into second, third, fourth or fifth grades because the producer has failed to realize the importance of properly producing and handling his eggs. The market egg of high quality is easily the most profitable one, and every producer of eggs should strive for it. Two points should be taken into consideration in placing a high-class egg on the market: 1. Production of the egg. 2. The handling of this product.

How to Procure Good Eggs

In the production of good eggs the stock is of utmost importance. Weak, sickly stock produces eggs that are of poor quality. Such eggs will deteriorate quickly. Discard the hens that lay too small or too large eggs, and eggs that are poorly shaped. If eggs selected for incubation are small, ill-shaped, of poor color and texture, so will be the eggs that are laid by hens hatched from those eggs.

The question of the quarters in which the stock is to be kept is also an important one. No matter how healthy the stock, if kept in poor quarters, it will become sickly and weak. The house should be roomy, well-ventilated, and allow an abundance of sunshine to enter. A good supply of dry, clean nesting material should be in all the nests at all times to reduce the danger of soiling eggs and breaking them in the nest.

Immediately after the eggs are gathered they should be graded and sorted. Take out all eggs in any way dirty. The egg with a dirty shell is one of the most objectionable factors of the egg industry. Its contents may be fresh and the egg itself may be large, but the dirt on the shell consigns it at once to the "seconds," and it will bring a lowered price in all markets. Dirty-shelled eggs do not store well and are therefore not available for holding when the surplus production is greatest. Often they scarcely pay the expense of marketing.

Do not wash dirty eggs and send them to market, for different forms of mold may result from packing the eggs damp. Washing also gives them the appearance of stale eggs by making them look glossy. Do not pack eggs that are cracked, for they will probably become broken before they reach the market and soil a number of other eggs. Pack the eggs according to size, placing the large eggs in one case and the small ones in another. Also sort them as to color, separating the brown eggs from the white eggs. Candle all eggs before sending them to market so that stale eggs, eggs with blood rings, checks, white rots, black rots, moldy eggs, eggs in which incubation has begun, etc., will not be put upon the market.

Following are five rules which might well be followed by all farmers and poultrymen in handling their poultry and eggs:—

1. Keep the nests clean; provide one nest for every four hens.
2. Gather the eggs twice daily.
3. Keep the eggs in a cool, dry room or cellar.
4. Market the eggs at least twice a week.
5. Sell, kill or confine all male birds as soon as the hatching season is over.

The raising of poultry, collecting and marketing of eggs, etc., has always been left, to a large extent, to the

Every 10c Packet of WILSON'S FLY PADS
WILL KILL MORE FLIES THAN $8.00 WORTH OF ANY STICKY FLY CATCHER
Clean to handle. Sold by all Druggists, Grocers and General Stores

farm woman. But in too many cases, poultry raising has been considered a side issue and the care of the chickens and the gathering of the eggs has often been left to the children on the farm. As a result no one knows just how many working hens are around Poultry Galley 2 moR ao qeH the farm. Often the eggs are gathered from stolen and dirty nests and taken to town and traded for groceries. If the eggs are sold on a "loss off" basis, by which only the good eggs are paid for, those eggs gathered from stolen nests will be candled out and the farmer will receive pay for only a small part of the eggs which he has brought to town.

Now is the time to make every effort to improve the quality of the flock, select the best layers (by the trap-nest or other methods), and discard the weak sickly stock.

CURING HENS OF BROODING FEVER

Am cnR pbq a.ih (FiR ..wk5e

What to do with broody hens is a problem that confronts many farmers during the spring and early summer. To be sure, a few are used to hatch and rear chicks, but the remainder are not only a nuisance but a source of loss during the time that they are not producing eggs. It is desirable that these birds be "broken up" as soon as possible. In the Laying Contest which the Connecticut Agricultural College conducts, a broody coop 1½x1½x3 feet and made entirely of slats is provided for each house. When a hen becomes broody she is shut up in this coop with no food but with plenty of water to drink. Three days of such confinement is usually sufficient to cure her of all desire to sit. The management feels that being in the same pen where she can see the other birds moving freely about the pen and eating at liberty will cause her to get over her broody fever sooner than she otherwise would. In extremely hot weather when such close confinement would perhaps be dangerous, the broody hens are simply turned into pens with bare yards.

At one of the contests referred to records were kept showing a comparison of the different breeds with respect to broodiness. The highest percentage of broody birds was found in the Rhode Island Reds and the lowest in the Leghorns. It is interesting to note, however, that when a Leghorn does go broody, she loses more time than a bird of any other breed. By time lost due to broodiness is meant the number of days between the last egg before and the first egg after a broody period. The average number of days lost by the average bird of any of the four breeds is perhaps the best method of comparing them on this character. Thus the average Red lost 39.9 days during her pullet year due to broodiness, the average Wyandotte 38.9 days, the average Plymouth Rock 24.3 days and the average Leghorn 3.1 days. Of more importance, perhaps, to the man who is keeping but one breed is the number of days the average broody hen will lose. Thus the average broody Red last 58 days, the average broody Wyandotte 62 days, the average broody Rock 56 days and the average broody Leghorn 32 days. Although the average number of days lost each period was 21.6 for the Leghorns as against about 19 days in the other breeds, the fact that only ten per cent. of the Leghorns went broody and those only 1.5 times on the average reduced the total days lost to a small figure.

In the case of the Wyandottes and Plymouth Rocks the highest percentage of broody birds was found in the buff varieties due, in all probability, to the fact that Cochin blood was used in their ancestry to obtain the buff color.

WINTER EGG SUPPLY

It is a good practice to do something new and different every once in a while. For instance, each spring one should try to have a new vegetable or fruit for the garden. This gives one fresh interest in gardening work and adds to the store of necessary food. Another good thing to introduce this year in the practice of putting down eggs. I think it is too much to expect that hens will lay in the depths of our cold winters, and a house without eggs is sorely handicapped. Nor does one need to be without eggs. The science of preserving eggs is so highly organized that the surplus of spring and summer months can be held over for winter with scarcely any depreciation. In each of the provinces the department of agriculture is prepared to offer the most complete suggestions on keeping eggs to any who are interested. Briefly, the preliminary arrangements are to separate all male birds from the laying flock as fertilized eggs will not keep as well as non-fertile. Then collect the eggs regularly. When fresh, put them into a coal cellar or other place that is free from the blazing sun and then get ready the preserving mixture. Experience points to two standard preservatives for eggs, namely, lime water and a preparation of "water glass" and water. The first may be made by dissolving lime in water and the latter is bought at drug stores. Most people should use the former, as it costs very little, and that is a prime consideration. A good plan is to get a barrel, cut it in two and make tubs. Put about ten pounds of lime in one of these and fill it up with water. Stir until the lime has dissolved, then put the fresh eggs into the water. From time to time this will have to be refilled, as the water evaporates, and as the lime settles add more when fresh water is put in. It is not much trouble to put down a hundred dozen eggs this way, and they provide a splendid variety in winter.

Sometimes eggs are rubbed with lard and packed in bran, but this does not prevent moisture escaping from the inside of the egg. Where one lives close to a cold storage plant the trouble of preserving may be saved by simply putting the eggs in storage. Such stores usually carry thirty dozen cases for ten cents a month. In any event, preserve some eggs and do it before the hot weather of July arrives.

Spanking Doesn't Cure!

Don't think children can be cured of bed-wetting by spanking them. The trouble is constitutional, the child cannot help it. I will send FREE to any mother my successful home treatment, with full instructions. If your children trouble you in this way, send no money, but write me to-day. My treatment is highly recommended to adults troubled with urine difficulties by day or night. Address

BEST CHANCE FOR PROFIT

Thousands of hens and pullets were sent to market last fall because their owners were of the opinion that they would receive no profit from feeding them high-priced grain. In many cases this view was correct. The consequence of such action is a scarcity of fowls and unprecedented high prices for eggs.

Eggs and poultry are bound to continue high in price. Next winter may see eggs selling for more than was secured the past season. For these reasons the margin of profit may be made greater than during past years. Farmers who can grow a large part of the feed for their hens are in a position to clear a very handsome profit.

A bushel of grain a year to feed a hen is the old-fashioned way of reckoning, but if fowls are confined in yards it will require nearly 100 pounds. In order to get a profit from feeding high-priced grain you must have early hatched, well-grown pullets and give them the best of care and attention.

CREMATE THE DEAD CHICKENS

There is only one safe method of disposal of the dead, and that is by burning. An ordinary wood fire does quite well, but an old carbide can or other such thing made over slightly, makes the job easier, more complete and less repulsive. Having procured the carbide can, make a hole in the bottom a little smaller than the hole in the top, and then on one side near the top make a door as shown.

Before starting operations, dig a small hole and set the can inverted over it. Fill with cobs or wood and soak with coal oil. Then drop the dead fowl in the top and ignite. When all has burned, nothing will be left but the ashes, which have fallen into the hole and may be then covered up. In this way only, can one safely handle contagious diseases in the chicken yard.

USE MORE OYSTER SHELL GRIT

We had a very interesting talk the other day with the buyer for a very large hotel, who also happens to be a keen poultry enthusiast. He was telling us that there is a great difference as a rule between the shells of the eggs produced by city poultry keepers and those produced by the farmers.

The eggs produced by the city hens as a rule are better shelled and keep longer than those laid by their country cousins.

This he affirms is due to the fact that the city hens are well supplied with shell whilst the others are not. This is one reason why farm eggs often arrive in a damaged condition when shipped by rail. The shells are poorly formed and quickly break in transit, consequently the producer does not realize the price he should were his eggs well shelled and in sound condition.—Farm and Ranch.

PEERLESS GATES

Down the road or far across the fields is often an "entrance," a mere hole in the fence, a constant source of danger to stock getting through. The best way to

Keep Your Stock Where You Want Them

is to provide real gates, strong and durable. All Peerless Farm Gates are of heavy open hearth steel wire on strong tubular steel frames electrically welded in one solid piece, and **braced like a steel bridge.** No sag, no rust, no wearing out. Ask your dealer to show you Peerless Gates, also Peerless Perfection Farm and Poultry fencing with the famous Peerless lock at all intersections.

SEND TODAY FOR CATALOG. It tells you how to put up a fence to stay put."

FOR HOME AND COUNTRY

This Department will be utilized to the best interests of the homes in the Maritime Provinces. Subjects relating to household science and all that stands for better homes and communities will be published on this page. The editors, Misses Saunders and Winter, of Fredericton, N. B., solicite your assistance in making this page a success and will be glad to publish tested recipes, household discoveries and other articles useful to the homemaker and women's organizations.

JUNE

By Theodore Harding Rand

Now weave the garlands for June's lyre
Their bowers of cloud whence odorous blooms are flung
Far down the dells and cedarn vales among—
See, lowly plains, sky-touching mountains aspire!
Now flash the golden robin's plumes with fire,
The bobolink is bubbling o'er with song,
And leafy trees, Aeolian harps new strung,
Murmur far notes blown from some starry choir.

My heart thrills like the wilding sap to flowers,
And leaps as a swoln brook in summer rain
Past meadows green to the great sea untold.
O month divine, all fresh with falling showers,
Waft, waft from open heaven thy balm for pain.
Life and sweet Earth are young, God grows not old.

WHAT IS WORTH WHILE?

Writen by Mrs. James E. Porter, Andover, N. B.

Only one life to live! We all want to do our best with it. We all want to make the most of it. How can we best get hold of it and accomplish the most with the energies and powers at our command. What is worth while?

Life is large. We cannot possibly grasp the whole of it in the few years that we have to live. What, then, may we let go and one what shall we lay hold, in order to live the fullest life possible and give back to the world some evidence that it has been benefited by our existence?

To begin with we may drop pretense Eternity is not good for shams. Whatever we really are, that let us be in all fearlessness. Whatever we are not, that let us cease striving to seem to be. Nothing gives such upright dignity of mein as the consciousness "I am what I pretend to me. My life shall be no vain mockery, but a reflection of true self."

We may drop worry. Let us not depress ourselves with the foreboding of future ill. Every moment of worry weakens us for our daily combat. It brings on premature old age and weakens our intellect. It makes us most uninteresting to our friends and deprives us of that strength o' mind and body which enables us to develop the best there is in us. It is an infirmity. There is no virtue in it. Seen in their true relations, there is no experience of life over which we have a right to worry. Ruskin says, "We are always given strength enough and sense enough for everything we have to do." It is not the lack of ability that often worries us, it is not our failures that distress us, so much as our idiocies.

We may let go discontent. In life I find two things that make for discontent. One is lack of harmony with our environment. The gods of fate have not been kind in placing us where our natures cannot blend in true sympathy with our surroundings, where our ideals mingle with uncongenial spirits. The other is dissatisfaction with our present opportunities.

The first may be overcome. The second may be put out of our lives, for present opportunities, if rightly used, are all that we need ask. Thoreau tells us that "opportunities are not far off, either in space or time, but right here and now at the door." Which of us can sit down at the close of a day, and say "To-day I have done all that was in my power to do for humanity and justice."

There are things in the circumstances of our lives that we can change. There are opportunities that our own efforts may enlarge. By strength of will and character we can conquer many of the difficulties that beset our career, and so conquering, be strong. I believe more and more that there is no impediment that cannot be overcome, no hindrance to usefulness that cannot be removed. We can never work well while there is friction in our lives, nor goin in our work that "beauty which is born of power and the sympathy which is born of love" of which Ruskin speaks.

We may let go self-seeking. As the waters fled away from Tantalus, so do the good things of life flee from the grasping and selfish spirit. The richest experiences never come to those who try to win them selfishly. If they do gain their desires, they find them as ashes to the taste. Selfishness kills out many human qualities and leaves the victim disappointed with life, hard hearted and unloved. But all blessings are in the way of those who, forgetful of self, try to be helpful to the world, and spend their lives in loving deeds.

Pretense, worry, discontent, self-seeking—these are the things that we may let go. Now, what are the things in life that are worth while, that we should lay hold of.

It is worth while to be wise in the use of time. It is with time that we purchase everything that life has of good. It is by the wise use of time that we make ourselves competent to live. The most reckless spendthrift in the worl is the one who squanders time. Money lost may be regained; friendship broken may be renewed; but what power can restore the moment that has passed, the day whose sun has set, the year that has been numbered with the ages past? The question of life is not "How much time have we" but rather "What shall we do with it?" "How shall we determine what things are worth giving time to?" Shall we let this priceless gift which nature has bestowed upon us slip away in haphazard deeds, or shall we adopt some systematic doing in our lives? Let us think about it. We cannot afford to lose a moment of our usefulness of the sum of our influence will be less than it might have been. Therefore let us not lose time in grieving, in dreaming, in regret, in idle talk. Life is made for some grand purpose—for work, patience, love, for bearance.

Let us lay hold of work. There can be no happy life without a strenuous, unremitting work in it. Work which occupies mind, body, heart and soul. But what work shall we set ourselves to do? How shall we find out in what direction our talents lay, and to what start out in life, and that reappear from time to time, as we see more of our possibilities.

We fear to make mistakes. We do not want to throw our powers away—to build walls of sand when we might have built monuments more lasting than bronze. Emerson says "Nature arms each man with some faculty which enables him to do easily some feat impossible to any other." Let us examine our capacities and gifts and then put them to the best use we may. Let us not try to escape our work, nor to shirk it. Above all, let us not fail to see it, but make it vital enough to strengthen our own character and inspire others. We shall never be too old for it, nor too feeble. It is for us, therefore, to use every moment of today as if our very eternity depended on its words and deeds. Oh, the remorse for the good we might have done and did not! Does it not bring pain and regret to the aching heart?

Let us lay hold of the happiness of to-day. Do we not go through life blindly, thinking that some fair tomorrow will bring us the gift we miss today? Poor mortal! when thinkest thou to be happy? Tomorrow? What is tomorrow? Is it not but another today? Knowest thou my heart, if thou art not happy to-day, thou shalt never be happy. To-day is given thee to be patient, to be unselfish, to be purposeful, to be strong, eager and work mightily. If thou doest these things with a grateful heart, thou shalt be happy. We are happy when we have done our duty, be the skies dark or fair, and if we would increase our happiness and prolong life, let us forget our neighbor's faults; forget the slander we have heard and the temptations; forget the fault-finding and give a little though to the cause which provoked it. Obliterate everything disagreeable from yesterday. Start out with a clean sheet for to-day and write upon it for sweet memory's sake,—only those things which are lovely and lovable.

Let us lay hold of friendship. Emerson says "To have a friend, you must be one." Seek how we may, we shall never find a friend without faults, imperfections, and ways that vex and sometimes grieves us. Strive as we will, we ourselves can never fully fulfil the ideal that is in our friends' mind. Yet, let us not give up friendship, though we have found this true. To have a friend is one of the sweetest gifts life can bring. To be a friend is to have a solemn and tender education of soul from day to day. One must forgive much, forget much, forbear much. Let us be slow to make friends, but, having once made them, let us pray that neither life nor death, misunderstanding, distance nor doubt may ever come between us to destroy our peace. Let us be true to our friends and then believe that they are and ever will be, true to us.

Let us lay hold of our common duties with courage and cheerfulness, with the determination and good judgment that insures success. Let us consider life at all points before we rush into a new phase of it, from which, once in, we may not soon withdraw. Most of us are bound with loving calls of toil, care and responsibilities which we must recogni e and obey. Stevenson says, "Each day brings us the petty round of irritating concerns and duties. Help us to play the man." Duty well defined and skillfully performed will make it possible for us to live our lives effectually, grandly. To be brief, let us say, "Whatsoever they hand findeth to do, do with all thy might."

Letting go the unworthy things that meet us, the things that do not make for better life, and taking loyal hold on time, work, present happiness, duty, love and faith, let us work for a present good, here and now, believing that we can reach the future only through the present. Let us so live in all true womanliness as to be an inspiration, strength and blessing, to those whose lives are touched by ours.

HOUSEHOLD DISCOVERIES

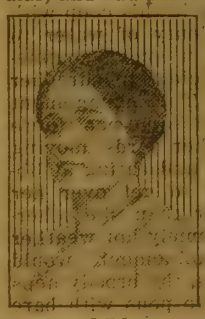
If you want to save both time and labor, iron your crepe de chene and pongee waists dry. They iron beautifully, perfectly dry and this does away with the idea that while they are damy they must be ironed.

Water drained off of rice may be used to starch clothes. This rice

PAINS IN SIDE AND BACK

How Mrs. Kelly Suffered and How She was Cured.

Burlington, Wis. — "I was very irregular, and had pains in my side and back, but after taking Lydia E. Pinkham's Vegetable Compound Tablets and using two bottles of the Sanative Wash I am fully convinced that I am entirely cured of these troubles, and feel better all over. I know your remedies have done me worlds of good and I hope every suffering woman will give them a trial."—Mrs. ANNA KELLY, 710 Chestnut Street, Burlington, Wis.



The many convincing testimonials constantly published in the newspapers ought to be proof enough to women who suffer from those distressing ills peculiar to their sex that Lydia E. Pinkham's Vegetable Compound is the medicine they need.

This good old root and herb remedy has proved unequalled for these dreadful ills; it contains what is needed to restore woman's health and strength.

If there is any peculiarity in your case requiring special advice, write the Lydia E. Pinkham Medicine Co. (confidential), Lynn, Mass., for free advice.

starch keeps for several days if kept in a cool place.

If you have a plant with leaves turning yellow, you may be sure there are worms in the soil. Place piece of an apple in the soil. The worms are sure to go to it. When you remove piece of apple you will also be removing the worms.

Never serve vegetables canned in tin in their own liquid. Drain and wash vegetables, then cook as desired.

It is a great improvement to add about ¼ tsp. of sugar and a slice of onion to canned peas when cooking.

To make baked beans canned in tin more palatable, fry together pieces of salt pork and onion, then add beans and heat together.

During warm weather when food spoils readily, corn syrup cans may be used for baking a small amount of beans.

A black silk skirt badly soiled by mud was cleaned with hot coffee and every stain removed. The coffee was first strained through muslin to remove all sediment, then freely applied to the spots and rubbed in vigorously. The entire skirt was sponged lightly with it, allowed to become partially dry and ironed on the wrong side. This treatment does not make silk stiff or shiny, but causes it to look fresh and new.

A QUEEN OF PIES.

She isn't versed in Latin, and she doesn't paint on satin,
She doesn't understand the artful witchery of eyes;
But, oh, sure 'tis true and certain, she is very pat and pert in
Arranging the component parts of luscious pumpkin pies.

She cannot solve or twist 'em—viz., the planetary system,
She cannot tell a Venus from a Saturn in the skies;
But you ought to see her grapple with the fruit that's known as apple,
And arrive at quick conclusions when she tackles toothsome pics.

She couldn't write a sonnet, and she couldn't trim a bonnet,
She isn't strictly bookish in her letter of replies;
But she's much at home, oh very, when she takes the juicy berry
And manipulates, quite skilfully, symposiums in pies.

—Elizabeth Gregg in American Cookery

FISH

Fruit of the wave! O dainty and delicious

In fish we have a food similar in character to meat, yet different from it in some ways. These points of unlikeness in the flesh of the two classes of animals correspond to differences in the natures of the animals themselves. The fibres of fish are looser than meat, more watery and have less connective tissue. Fish is of high food value being rich in proteid. It is not stimulating like meat because it lacks extractives but it is easily digested.

How to know a fresh fish.—In a fresh fish the gills are a bright red, the flesh is firm and elastic, and the eyes bulging and bright.

Baked Fish

Clean fish, rub with salt, fill with stuffing and sew edges together. Put pieces of salt pork across fish. Wrap tail in waxed or greased paper and skewer fish in shape or letter S. Dredge with flour. Baste every 10 min. Fish requises about 10 min. to the lb. and 10 minutes extra. It is cooked when meat separates from the bone. Garnish with parsley and lemon.

Salmon Hash

One can of salmon flaked fine, 1 cup rolled cracker crumbs, 1 cup milk, 1 tbsp. butter, add cracker crumbs, stir, then add flaked salmon. Stir these together then add pepper, salt and a dash of cayenne. Mix ¼ tsp. mustard with the oil from the salmon and stir this into the mixture. then add milk. When the whole is thoroughly heated through and thick it is ready to serve.

Creamed Salmon

Drop one can of salmon in hot water and while this is heating through, fry together 2 tbsp. butter and ½ onion sliced fine, stir into this 2 tbsp. flour and seasonings and 1 pt. milk. When cooked add liquor from the can putting into the pan it was baken in, 1 can of salmon and one can of peas that have been washed and drained. Arrange fish on platter and pour sauce around it. Garnish with parsley.

Baken Canned Salmon

Drain liquid from salmon, remove skin, season salmon with salt and pepper. Over the salmon place an inch thick layer of well seasoned mashed potatoes. roll in buttered crumbs. Bake ½ hr. in hot oven. basting with a little butter and cream. Place carefully on platter and place around it a cream gravy made by putting into the pan it was baken in, 1 pt. of milk. the juice of the salmon mixed with salt and pepper and 2 tbsp. flour. Strain. Garnish a lemon point with each person.

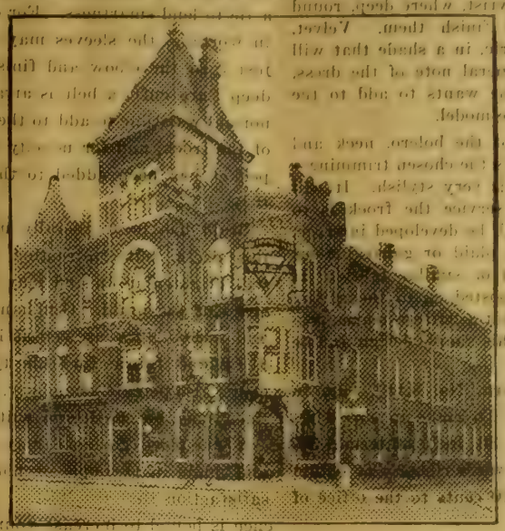
Fish Cakes.

1 c. saft codfish, 1 egg, 2½ c. potatoes, ½ tbsp. butter, pepper.

Wash fish and break in small pieces, pare potatoes and cut in pieces. Cook together in boiling water. When potatoes are soft, drain and shake over fire until dry, mash thoroughly, add beaten egg, butter and pepper and beat until light. Drop by spoonfuls in deep fat. Fry until a golden brown.

The Transformation

Right in the heart of the great city of Toronto, in the centre of the principal business district, close by the cross-roads of main traffic, stands the "second longest bar in all Canada." Observers say they used to count hordes of men entering this stronghold of the Traffic. Were the frequenters of the bar better men when they came out?



On September 16th, 1916, Prohibition went into force in Ontario, and, of course, the bar lost its license. On the 16th of April, 1917, the old bar was busier than ever! But what an arresting, beautiful transformation! Would that you and your sons could have been there to see the sight. The old bar-room was a bevy of flowers. Fifty fair ladies served refreshments to Toronto's most prominent citizens and their wives, and not one of them all but was proud to be seen in the old barroom.

The aching, worrying hearts of the army's mothers are relieved now when they see their sons enter this building—for the old bar is helping to save men now instead of ruining them.

The hotel is now the "Y.M.C.A. Soldiers' Club," one of the Young Men's Christian Association's long chain of clubs, marquees, huts and "dug-outs" extending from Vancouver to the firing line in France—the helpful sentinel-posts that safeguard our precious soldier men and boys wherever soldiers are congregated. To the Y.M.C.A. Canada owes a debt of gratitude she never can adequately repay.

Like New Brunswick, the Traffic in Ontario has the opportunity, after the war, of putting Prohibition to the test at the polls. But Prohibition in Ontario is being enforced, and the old strongholds of the Traffic—the long bars we mean—are one by one being turned to useful purposes. Many of the hotel buildings that depended for existence upon bar trade are now devoted to commercial enterprises—constructive instead of destructive.

Does New Brunswick want to return to the destructive license system, and again be a partner in the old firm of John Barleycorn and Company, Limited?

Or does New Brunswick want to maintain Prohibition for ever? If so, Enforcement must be province wide, must be both strict and effective.

Help to Enforce Prohibition

Every man and woman in this province shares the responsibility for the proper enforcement of Prohibition—not the officers of the law alone. *Your* duty is clear.

The Maritime Farmers' Fashion Dept.

GIRL'S DRESS.

By Anabel Worthington.

Fashion surely plays fair with the junior in giving a design like this in a dress. The separate bolero is the feature that counts—perhaps there is none more successful than this style among the models offered for growing girls.

The waist is very simple, cut with a rather high, round neck and with fastening at the back; over it the separate bolero is worn. A ribbon girdle is draped negligently at front, after covering the joining of the waist to a one piece gathered skirt. The sleeves are set in with a slight fulness and reach to the wrist, where deep, round cuffs of material finish them. Velvet, satin or other fabric, in a shade that will blend with the general note of the dress, may be used if one wants to add to the effectiveness of the model.

For the edges of the bolero, neck and sleeve cuffs braid is the chosen trimming—it looks well and is very stylish. It will depend upon the service the frock is to give whether it will be developed in serge, wool poplin, wool plaid or gabardine—or velveteen, duvetyn or similar fabric. If you are one not posted as to the saving and satisfaction that a pattern makes possible, begin with this simple design and be convinced.

The dress pattern, No. 8,119, cuts in sizes 6-12 years. To make in size 8 requires 3⅛ yards 36 inch material, 3⅝ yards braid and 2 yards ribbon. To obtain the pattern send 10 cents to the office of this publication.

LADY'S HOUSE DRESS.

By Anabel Worthington.

It is during the busy hours that the supreme test of a woman's charm occurs, so if you want to come out with flying colors see to it that your house dress does you full justice. Of course, you will make it yourself, for you will then have the color that is becoming and the little detail touches that express you.

For appearance and service it is our opinion that the design illustrated under No. 8,173 stands out as one of merit and you will no doubt agree with us. The waist is on the style of the plain shirt waist and slightly gathered where it joins a three gore skirt, the fulness of which is gathered under a belt of contrasting goods that is stitched on at the joining. A sailor collar finishing the V neck may be of the dress material or in contrasting note and long or short sleeves may be chosen. Some women prefer to have detachable collars for such dresses. The pocket stitched to either side of the skirt is a convenience and an added attraction, especially if in contrasting color.

Linen, gingham, percale in striped or figured effect and lawn are among the favored fabrics for developing. One need not be clever with the needle to reproduce this design, for its lines are the simplest.

The dress pattern No. 8,173 cuts in sizes 36 to 44 bust.

To make in size 36 requires 4¾ yards 36 inch material, with ¾ yard 36 inch contrasting.

To obtain the pattern, send to the office of this publication.

LADY'S HOUSE DRESS.

By Anabel Worthington.

Simple in cut, smart in detail touches, neat and becoming—all of this you want your house dress to be. In the picture you see a garment with these features combined.

The dress is cut in one piece, the waist being perfectly plain, with a V neck outlined by the new style of collar, and with a tie to lend smartness. For convenience in working. the sleeves may be made to just turn the elbow and finished with a deep flare cuff; a belt is arranged about normal waistline to add to the trim effect of the frock, and for novelty the triangle pocket has been added to the skirt section.

Braid has been liberally used to trim this dress, but contrasting color goods will brighten it up and may be used instead of the braid. Gingham in narrow and wide stripes, as well as in checks, is a favored fabric for this type of garment; also percale, chambray, galatea and linen may be considered suitable.

A one-piece garment may be cut out and made in a couple of hours and the satisfaction that results from

ence is bound to increase your interest in patterns.

The dress pattern No. 8,118 cuts in sizes 36-42. To make in size 36 requires 5⅝ yards 36-inch material and 5 yards braid.

To obtain the pattern send 10 cents to the office of this publication.

GIRL'S DRESS.

By Anabel Worthington.

This is the time to visit the shops for the new spring fabrics if you have a girl going to school, for of course she has outgrown last year's frocks and you will need to make a few at least to last her for the school term.

A charming example of what is really good style for a girl up to 14 years of age is shown by the illustration. An interesting feature of the design is having the deep yoke and panel cut in one piece, the back being the same as the front. The back and front side sections are gathered where they join the yokes and a plait is made at each seam where they are joined to the back and front panels. The neck opens in a V and is collared in sailor style with contrasting goods; the long sleeve is cuffed to match. Except for a few buttons, the only trimming, if it can be called that, is a belt holding the fulness at the sides—it is of material in harmony with the collar.

Fine cords are a marked feature of the new fashionable cottons; a heavy mercerized cotton poplin with woven colored stripes is a distinct novelty; then the usual linen, gingham and like weaves are also to be seen. Now that nearly all schools teach sewing a girl of 12 years can easily manage a pattern that is named and marked and she will enjoy having a dress like the one pictured grow under her own hands.

The dress pattern, No. 8,174, cuts in sizes 6 to 14 years. To make in size 10 requires 3¼ yards 36 inch material and ½ yard 36 inch contrasting goods or 3⅝ yards all one material.

To obtain the pattern send to the office of this publication.

Price 15c Each.

See Opposite Page for Ordering

CLEANING AND STORING FURS

Light or white furs can be cleaned with corn meal or flour. Place corn meal in oven until heated, then rub into the skin of the fur, shaking it out when soiled and continuing until the flour or meal is clean. Never handle furs roughly but they should be beaten. Take a .coarse comb and comb every inch of fur shaking from time to time.

Seal each article in a newspaper or in a moth-proof bag or get tarpaper and make flat bags sewing on machine and seal article in it. Never let woolen articles stay on the line until late in the evening as insects may crawl into them for the night and make trouble later on. It pays to put up the screens early even if not necessary for flies. It may keep moth out of rugs and carpet. The box-couch will make a cedar chest by stuffing the cracks with cotton saturated in cedar oil and the addition of a few new cedar shavings.

CHOOSING OILCLOTH.

In choosing oilcloth for floor covering notice the back. Oilcloth is merely burlap given several coats of coarse paint. The design is put on by wooden blocks, each block carrying the design colors. If backing of oilcloth shows an open woven burlap it will not give good wear unless it is painted and varnished about every three months. In fact, even best grade oilcloth should be frequently varnished. Floors upon which linoleum or oilcloth is laid should be evened up with a covering of old carpet or carpet paper and all cracks filled with sand. The best of either will soon wear over sunken or protruding places in the floor.

HOME-MADE SOAP

One-pound can of potash; five and one half pounds of grease (strained); one half cupful of ammonia; one-half-pound package of borax. Dissolve the potash in three pints of cold water. This causes the water to boil. When cold, stir in the melted grease, then the ammonia, and lastly the borax, stirring constantly. Pour into pasteboard boxes to cool, and when cold, cut in squares.

A good scouring soap can also be made by adding lastly a small quantity of fine, white sea sand and stirring throughly. Finely ground oatmeal added to the original mixture will make an excellent toilet soap.

Real Home Made Pie—

Yes, Ma'am!
Real homemade Pie!

With top and under crust that truly melt in your mouth—and a generous filling of your own delicious homemade preserves or home-grown fruit.

That's a pie worth eating, and worthy of your baking, and it's the kind of pie you can make every time with

BEAVER FLOUR

MILLED OF BLENDED WHEAT

"Beaver" Flour equals any of the "special pastry flours" because it is, in itself, a special pastry flour—being the choicest Ontario fall wheat, blended with western spring wheat to give it strength.

This is why Pies, Cakes, Cookies, Tarts, Doughnuts, Buns and Fancy Pastry —when made with "Beaver" Flour—are so light, so flaky, so uniformly good.

This is also why the Bread and Rolls—made with "Beaver" Flour—have a delicate, nutlike flavour that is totally lacking in western spring wheat flours.

Just try "Beaver" Flour for anything you are baking—and see what happy results you get, every time.

DEALERS—write for prices on Feed, Coarse Grain and Cereals. 200

How to Order Patterns.

Order by number, giving age or measurement as required, and allowing at least ten days to receive pattern. Also state in which issue pattern appeared. If two numbers appear for the one suit, one for coat, the other for skirt, thirty cents must be sent. Address Fashion Department, "The Maritime Farmer, Sussex, N. B. Be sure to sign your name when ordering patterns. Many forget to do this.

Positively no patterns will be sold under 15 cents each, owing to advance in cost of same.

When ordering, please use this form:—

Send the following pattern to:

Name .....

Post Office.....

County .....

Province .....

Number of Pattern.....

Age (if child or misses' pattern).....

Measurement—Waist .....Bust.....

Date of issue in which pattern appeared. .....

MODERN EQUIPMENT FOR FARM KITCHEN

Wives of farmers need not worry because of inability to obtain kitchen help. Sp-to-date equipment that will take the place of a helper may be purchased at comparatively low cost.

Of all labor saving devices, water piped into the kitchen is most essential. Although everyone cannot afford an expensive water system with bathroom equipment there are devices for bringing water into the kitchen and providing for its disposal, that can be installed at small cost. No woman should be expected to do the house work without this convenience.

Next to carrying water in and out of the house, the hardest work for the housewife is keeping the family supplied with fresh clean clothes. For this purpose she needs every modern improvement in laundry equipment. With the power washer now on the market she could have one operated by a gasoline engine or by electricity. The electric iron where available should take the place of the old-fashioned iron which necessitates many steps and much heat while doing the ironing.

MOTHER'S TOOL CABINET

Directly over the stove wood box in a farm kitchen in Dundas County, hangs a tool cabinet, out of the way and many a step it saves the busy housewife. It is forty-three inches high, twenty-five inches wide, nine inches deep, has one door and five shelves. It is screwed to the wall in such a way that it can be moved easily, if desired. Many things have a habit of finding their way to these shelves, but the chief things that belong there are several hammers, screw driver, pliers, tack pullers, nail puller, assorted nails and tacks, screws, wire twine, cans of varnish, paint, floor dressing, and the like. Scarcely a day passes when someone doesn't need one article or another from mother's tool cabinet.

Use more time and lower heat in cooking to develop flavours and to secure all the value in the food.

THE LAW OF KINDNESS

1st. Public health requires kind treatment to give us wholesome meats and milk and milk products that are not poisonous.

2nd. Agriculture requires the protection of our insect-eating birds and their nests.

3rd. Gratitude requires it for the services they render us and the happiness they bring into our lives.

4th. Duty to God who created and gave them requires it.

5th. Because it adds to the happiness of every human being through life to love and be kind to the lower animals.

6th. Because it has been proved in mnuerous schools of various nations that those taught to be doing kind acts daily to the lower races—feeding the birds, patting the horses, talking kindly to all sensitive creatures, etc.—become in all the relations of life, better men and women. —Geo. T. Angell.

The worst kind of failure is the failure that is the result of only half trying.

Make your FENCEPOSTS ROT-PROOF

DID you know that the ordinarily good fence post which you are accustomed to replacing every four or five years could be made to last 20 years? Creosote treatment does it. And Grade-One Liquid Creosote Oil brings this advantage right to your door because it is creosote in such form that the average home owner and farmer can use it.

Barrett's Grade One LIQUID Creosote Oil

The biggest point about Creosote Oil is that you can apply it by brushing or dipping. No cumbersome, closed-cylinder method. Just as simple as painting. And it penetrates deeper than any other preservative. Stop those costly renewals. Use this wonderful preservative on all wood work exposed to earth or dampness.

Carritte-Paterson Mfg. Co., Limited

FEEDING BABY.

How frequently should the baby be fed? This in a very common question among mothers, and one which is so rarely answered correctly. If a mother asks her neighbor this question she frequently gets the reply, "Oh! I feed my baby just whenever he wakes up or whenever he cries for it." Unfortunately this is the method of feeding the baby adopted in the vast majority of homes. Almost any cry from the baby is interpreted as a hunger-cry, and he is fed forthwith. It may be of interest to note here that a baby cries from overfeeding as well as from hunger.

In a certain number of homes the baby is fed fairly regularly with an approximate interval of two hours between feedings—or about ten times a day. In a smaller number of homes the baby is fed every three hours, or seven or eight times a day, and in comparatively few homes the baby is fed every four hours, or five or six times per 24 hours. In most cases the latter method is the correct one scientifically and the one to which the mother should rigidly adhere. In the following paragraphs we will consider the reasons for this conclusion.

Let us understand, in the first place, that we are speaking of infants under 12 months of age. In no case should a baby be nursed for more than 12 months. Frequently a mother will nurse a baby for a longer time rather than wean him during the summer months. This is poor management. If proper care be used, the danger of sickness from weaning in summer is slight.

The most common form of indigestion in the breast-fed baby is dyspepsia. By this is meant a condition with symptoms of colic, diarrhoea, vomiting, and a slight rise in temperature. The chief cause is overfeeding, whether this occurs by giving too much at a feeding or from nursing too often. The condition is most frequently seen among babies who are fed irregularly and at too short intervals. If the weight of these babies is noted it will be seen that at first they gain very rapidly, then remain constant, and lastly, begin to lose weight. Such babies will then require medical attention.

Some interesting comporisons of the weights of six hundred babies fed from birth every two hours and every four hours, respectively, have been made in Toronto with the following results. For a while the baby fed every four hours remained somewhat lighter in weight than the baby fed every two hours. This condition lasted until the babies were about four months old. Then the four-hour baby began to catch up with the other one, and was on even terms with it at six months. Thereafter the four-hour baby got ahead of the two-hour one, and by the end of nine months he weighed about one pound more than the two-hour baby. This was certainly an indication that he had not been starved. Furthermore, the four-hour baby had been comparatively free from digestive disturbances all that time; that is to say, he had a much better start in life. Babies fed every four hours rarely had dyspepsia.

Another point worthy of consideration is the effect on the mother of fewer feedings. The longer feeding interval will appeal to her in two distinct ways. First, the mother may not be sufficiently robust to nurse the baby every two hours. Again, the mother may have other duties to perform, which will prevent her nursing the baby every two hours. In both these cases the baby would usually be weaned, thereby decreasing its chance of living perhaps ten times. Many of these babies would not be weaned, but would have the benefit of the breast milk if the mother only understood that feeding the baby every four hours would be quite sufficient to meat all requirements.

For these various reasons we are justified in concluding that all normal babies, from birth up to the end of the first year, should be fed every four hours. Most of the above arguments apply equally well to those less fortunate babies who are fed on other than breast milk—From Toronto Civic Health Dept. Bulletin.

YOUR OWN JUDGMENT CAN BE TRUSTED

You have investigated the matter of business training. You have become convinced that business training offers better returns in money, position, and power than any other career.

FOR THE BENEFIT OF OUR HOUSEWIVES

Washing in cold water when overheated is a frequent cause of pimples.

It is said a wart can be removed by touching it several times a day with castor oil.

Never butter your pieplates, but drege them lightly with flour.

Cover raisins with water when stoning them. This prevents stickiness, and cleanses the raisins.

Cut the old table linen into small pieces and keep it in some handy place in the kitchen to use in greasing cake and bread pans, then burn. This saves times and greasy fingers.

It is good economy to take time to keep the hands in good condition. Use small mops, brushes and paddles for every possible kind of work.

People troubled with chronic sick headache will be glad to know that sleep, if taken at the psychological moment will prevent the attack. If the subject of sick headaches will watch the symptoms they will note that it begins with a feeling of weariness and heaviness. This is the time to sleep an hour, or even two, and it will eventually prevent the headache. When the attack is fairly under way sleep will not prevent it.

Have old gloves for slipping on when doing rough work, and keep some good lotion to rub well into the hands after the work is done. Lemon juice is good to remove stains, and pumice stone for scouring grime off the hands. It is always the part of wisdom to take the very best care of these, our bodies.

When a silk gown becomes accidentally spotted with grease, rub the spots well with magnesia, entirely covering them, then hang the dress away for several days. Then brush off the magnesia and rub the spots well with a soft flannel cloth, and you will find the spots have disappeared.

"ACME" STARCH

For all fine starching, use "Acme"—white or blue —it does perfect work. In 1 and 2½ lb. packages.

THE CANADA STARCH CO. LIMITED, - MONTREAL. 37

AN ACCOMPLISHMENT REALLY WORTH WHILE

It is a great thing and a good thing to be able to keep sweet individually, but for the people of a community to be able to keep sweet is a far greater achievement. To be able to disagree with a friend or neighbor on community affairs, social matters, politics, etc., and to still maintain friendly relations with them and regard for their honest convictions is an accomplishment really worth while.

It would be a rather monotonous old world if everybody thought alike;

Lend Your Profits to Your Country

PRESENT prices for agricultural products ensure good profits to the farmer.

To pay war expenses the Government needs these profits, and will pay you over 5% interest on them. Sir Thomas White, Minister of Finance, says: "A War Savings Certificate in every Canadian home will help to win the war."

For every $21.50 you loan to Canada now, you will receive $25 at the end of three years. War Savings Certificates are issued in denominations of $25, $50 and $100, selling at $21.50, $43 and $86, respectively, and may be purchased at any Bank or Money Order Post Office.

"Make Your Land Support its Defenders!"

The National Service Board of Canada,
OTTAWA. 30

and it should be remembered that neighbors have as good a right to their opinions as we have to ours, and that they are quite as likely to be right as we are. A friendly controversy with one who differs with us will often help us to get a line on our own misconceptions, and cause us to view matters from a different angle.

We should try to remember that no one individual has a monopoly of all the intelligence and judgement and good sense in a community.

The reason why some people grow narrow and cranky and disagreeable as they advance in years is becuse they persist in adhering to their own opinions, and are intolerant of any one who presumes to differ with them. A due regard for the honest convictions of our neighbors and friends will often enable us to broaden our own outlook, and to keep in the middle of the road ourselves.

It is not that we are lacking in friendliness, for we are at heart a really friendly people. In sickness and in sorrow and even in financial reverses we are quick to proger sympathy and assistance, but in order to maintain neighborly sweetness we must do more than this. We must have a real regard for what we may term our neighbor's weakness, and respect their opinions and convictions as we would wish them to respect our own.

In all our relations with our fellow men we must be open minded and tolerant, and refuse to allow a difference of opinions to rob our neighbarly friendship of all its joy and sweetness.

BINDER SATISFACTION

Your Binder should last you many years—it should cut any crop—it should be light in draft and easy to run. It will be all this if it's a Frost & Wood.

Just remember it's only a small part of your crop that represents your net profit. All the rest goes to pay your expenses. You must harvest every straw if you want to make a profit and do more than just make expenses.

Buy a Frost & Wood Binder and you'll be able to handle any kind of a crop—tall, short or lodged grain. The hardest work won't discourage it.

It's easy on horses. Carefully fitted Roller Bearings in every working part insure light draft. Eccentric sprocket wheel—a Frost & Wood feature—eliminates strain on the binding attachment parts and makes "smooth" cutting.

A Frost & Wood Binder is sure cutting, sure elevating, doesn't choke or thresh the grain, is sure tying and splendidly finished. Levers are all conveniently placed, so inexperienced or "young" help can operate a Frost & Wood successfully.

Write today for interesting folder to our nearest Branch or see our nearest agent. Built in 5′, 6′, 7′ and 8′ sizes.

TRURO ST. JOHN CHARLOTTETOWN

WHY BOYS ARE ENCOURAGED TO LEAVE THE FARM

"Stay in the country where you will have plenty to eat and lots of air," has been the advice handed out to farm people for so long that many a lad without much thought on the matter considers himself doomed, and settles back to receive whatever fate many hand him. His position is fairly secure, and no doubt the arrangement is quite Utopian in nature. However, it is not permanent. When suddenly compelled to take charge of the farm, through some unforeseen circumstance, many a boy has failed to make good. The fault usually lies in either the boy or the father, or both. The chances are the boy has been doing his share of the hand work, but practically none of the head work connected with the farm.

"You take the milk to town," says the father, "and I will set the grain and get things ready so you can sow that wheat when you get back." The boy does as he is told, and has learned nothing new. He dosen't know for sure whether he is sowing six pecks to the acre or twice that amount, although it is a matter of considerable importance in the success of the crop.

Things could be explained as they are being done, but in many cases they are not. Farmers are hustlers. To them it seems a waste of time to have anyone idle. They wouldn't hire a man to whom they had to explain things. If anyone doubts it, let him take a man who can not hook-up a team, out on a farm, and see how long he will stay with some men. Much less would farmers think of allowing their sons to stand around long enough to find out some of the fine points of the business. It is questionable if this is the best way of accomplishing work. The boy's interest in such matter is worth far more than the minutes gained by hurrying them along. Furthermore, there will be more and better work done by the end of the season if the boys are let in on a little of the inside stuff. Boys who are properly interested in their work will not be satisfied otherwise. By merely going through a cycle of motions in doing the chores, not much information can be gained.

There is a limit to specialization, it is being found, and the concentration of the father on the head work and the son on the hand work is not conductive to the development of the boy. The boy who is properly interested will tarry a few seconds when his father says, "John, you water the stock while I mix up the feed," and at least get the principle of the thing. If the father has any objections and can not be made to see the light, the boy may well doubt the feasibility of remaining at home. A young man should get into a work where he can all the time be adding something to his store of knowledge. If farming does not give opportunity for enlargement, there is something the matter with it, or at least with the way it is being conducted.

Is there anything to be learned from the old-fashioned farmer? Many a stockman who has not studied chemistry has the balancing of feeds to perfection. He may know little of carbo-hydrates and proteins, but he does understand palatability and balances his feeds satisfactorily to the animal, which is after all the essential thing.

In the army, officers are expected to have some knowledge of the office next above them; and the principle might well be adopted on the farm, along with some other good business methods—like the keeping of itemized accounts—which are coming to be employed in rural work. The father should let the traces slacken once in a while, and get away from the farm, leaving the responsibility on his son. It would broaden both. There is, of course, little reason why this cannot be done; if the conditions mentoned are not remedied, it is one reason why he boy should leave the farm.

W. J. HOLT,

DON'T OVERDO.

More than half the ill temper and irritability displayed by woman is due to fatigue, not only of the body, but of the nerves. Every woman should learn how advisable it is to rest daily, and to rest in the proper way. After a tiring day, whether it be of housework, looking, after the children shopping, or paying calls, half an hour's rest properly taken will work wonders.

Paroid Roofs First Laid in 1898

NEPONSET **Paroid** ROOFING

Same Roofs Still in Service

PAROID is so good that the name has come to stand for the best kind of roofing. Complimentary, but dangerous! It means that for your own protection you must look for the name Paroid on every roll you buy. Then you are sure of the roofing that is approved by the National Board of Fire Underwriters.

SAVE MONEY

Look for the Roll with the PAROID Label

Once laid, a Paroid roof is weather-proof and fire-resisting for years to come. The saving on repair bills alone ensures the economy of Paroid, to say nothing of the absolute protection to your stock and crops.

TROUBLES OF THE AMATEUR GARDENER

(Continued from last issue)

Weeds sometimes give a little trouble in the garden. These are very small at first—so small that it does not seem possible that they could ever crowd out the rightful occupants of the garden. In the hot noon sun they seem to have disappered altogether.

But go out early in the morning when the dew is still on and there they are again, making the garden look like a farm. Then no matter what you have to do, get busy with the hoe, for verily the old proverb applies here: "A stitch in time saves nine." But even if there are no weeds to be seen it won't hurt to use the hoe and break up that crust that has formed on the surface of your garden.

Rich Soil Necessary

As a general principle those gar den crops that have the greatest nu tritive value remove from the soil a greater amount of plant food, than those lomer in the scale of foods, peas and beans being an exception to this rule. These plants leave the soil richer in notrogen and therefore do not require supplies of this ele ment.

With the above instance as an exception nitrogen, potash, and phosphates are the foods that must be supplied to the soil.

These elements of plant food which are removed by growth, can be returned to the soil in the variuos kinds of animal waste; manure, different forms of bone, etc., in mineral compounds, green manures, and a very small proportion in the inedible parts of the vegetables grown.

The elements contained in these substances are released as plant food rapidly or gradually according to the form in which they are applied. Where rapid growth is demandeu, fertilizers that decompose rapidly are essential. Of the various kinds of animal waste, poultry manure ranks first is this respect. Its manurial properties can be retained by placing with layers of earth. Stable manure is valuable for later effect after de cay has liberated its elements. It is sometimes very injurious when applied fresh to delicate plants.

This form of manure should be well rotted and applied and worked into the soil before cropping. In addition to this, quick acting fertilizers should be applied as they are needed by the plants.

Quick acting fertilizers whose elements are in proportions suited to different vegetables give satisfactory results with judicious use. These can be best applied by sprinkling on the surface before cultivating. Nitrate of soda, used to stimulate leaf growth is best applied during showery weather. It should not touch the foliage. I have said that peas and beans do not need nitrogen, but they do want lime and potash. Beets want all three. Turnips require large proportions of phosphates and potatoes need potash.

Onions require heavy feeding, with nitrate, potash, and bone meal.

How to Overcome Drought

Besides the damage done in our gardens by insects and plant diseases there is another enemy whose devastation is very marked at times, and this is drought.

If one sets out 100 cabbage plants and the cut worm gets ten of them, root maggot another ten, and caterpillars, etc., ruin another 20, we should be justified in raising a cry against garden pests for the loss would be 40 per cent. But it is a fact that the 60 remaining plants in a wet season would give a greater yield than the whole 100 in a dry season, for each plant would probably only attain half its normal weight. There is not one dry season in fifty that plants in the open garden get all the water they need, and every day they go thirsty, though not enough to check them, means a loos in crop. As this loss is not visible, it usually passes unnoticed. It will be seen therefore that we must not trust to luck and the weather as regards this matter of moisture. Now the two ways to combat this great invasion, drought, is by cultivation and irrigation. Cultivation has much more to do with keeping moisture in the soil than most people imagine.

I have not the space to go into the scientific reason for this. Suffice it to say that water leaves the soil in three ways, by soaking down to the lower levels of the subsoil, by running off the surfae especially on slopes, and by being drawn up into the air by capillary attraction as evaporation. It therefore becomes evident that in our cultivation we must aim to make the soil sponge-like and moisture-holding that its storage capacity may be increased We must also keep mellow surface into which rain will soak quickly when it falls and we must keep the moisture that soaks in from rising to the surface to be evaporated by sun and wind. The first ccndition is attained by deep digging or plowing, the second by deep cultivation with the hoe or harrows, and the third by keeping a fine mulch of loose dust on the surface.

Of the three ways in which water is taken from the soil, two of them usually only care of a surplus that we cannot use, that of evaporation is the one that concerns us. Few people realize the enormous amount oi water that is removed by this means. Throw a can of water on a dry place on a sunny day and see how quickly it disappears—all by evaporation, for if you examine the ground you will find it has not soaked into it. Then figure out how much is being evaporated every hour of every sunny day week after week from your garden.

The way to prevent this is never let a crust form from the day you plant the garden. Especially after every rain should you cultivate.

Now as regards watering. The ordinary watering is worse than useless. Unless enough water is applied to soak down into the soil the results are a crusted, packed surface and roots attracted up to the hot top-soil. Water can be applied either by automatic sprinkler or from the open hose where there is not sufficient force to wash out the soil.

Applied towards evening or in cloudy weather it is most effective.

Avoid watering during hot sun if possible. It is possible to overdo the watering. One good soaking a week should be sufficient, if enough is put on to represent one inch of rainfall, that is one inch deep over a level surface.

NATIONAL SERVICE AND POTATOES

By G. E. Sanders, Dominion Entomological Laboratory, Annapolis Royal, N. S.

In ordinary years the man who planted potatoes and then neglected spraying them and consequently got only half a crop of potatoes that rotted soon after storing, was only regardede as an enemy to himself and family. This year with potatoes seed very scarce and expensive and the prospect of a short crop of all food stuffs, on account of the scarcity of labor and seed, the man who neglects to spray his potatoes is as much a public enemy as the man would be if he dumped a few barrels of seed potatoes over the wharf, in this year of seed famine and impending food shortage.

The entire cost of spraying an acre of potatoes five times in a commercial way is $8.05. In a small way it will perhaps cost one fourth more.

The average increase in yield per acre, caused by spraying, taken over a period of ten years at the N. Y. Exp. Station was 97.5 bushels. Five thorough sprayings on Prince Edwards Island in 1915 gave an increase of 97 bushels per acre. 97 bushels of potatoes for an expenditure of $8.05, or a bushel more of potatoes for every ten cents worth of spraying material used seems almost miraculous in these days of $2 per bushel potatoes, yet that is the opportunity that the man who neglects to increase his crop by spraying is losing.

Potatoes should be sprayed five times with Bordeaux mixture to which a poison is added to kill the bugs.

Preparation of Bordeaux Mixture for Potatoes

Dissolve 6 lbs. of copper sulphate in 20 gals. of water, slake 6 lbs. of fresh stone lime and make up to 2 0gals. of milk of lime. Pour them by alternate buckets into the spray barrel, adding poison either:

4 lbs. lead arsenate
½ lb. paris green
1 lb. arsenate of lime

or some of the proprietary poisons as directed, and spray on the vines.

A shorter and easier method of making Bordeaux is by using the hydrated or prepared lime. In using this proceed as follows: Dissolve 6 lbs. of copper sulphate or bluestone and pour it into the 40 gallon spraying barrel, weigh out 6 lbs. of hydrated lime, fill the barrel nearly full of water, dump the lime powder into the barrel and

"Astonishing how my

Strength and Fitness

came back," says Mr. Inman, a Winnipeg business man, cured by Dr. Cassell's Tablets.

"It was astonishing how my strength and fitness came back," says **Mr. G. C. INMAN, of 330, HARCOURT STREET, STURGEON CREEK, WINNIPEG,** for many years a well-known man in the business life of Canada. Mr. Inman continues: "It is about three years now since I first used Dr. Cassell's Tablets. I was terribly run-down and weak. Sometimes I felt I should have to leave off altogether, my work was such an effort to me, I ate little, I had no appetite, and I suffered if I forced myself to eat.

"My nerves of course were in a bad way, and my sleep very disturbed. Everything, in fact, pointed to a nervous breakdown. It was then a friend told me about Dr. Cassell's Tablets, and I got some to try. The first result was that I could sleep at nights, and then my health rapidly improved. It was really astonishing how my strength and fitness came back.

Mr. G. C. Inman.

"I may add that some time ago my mother was very ill with pernicious anæmia. I urged her to take Dr. Cassell's Tablets, but she would not, so I crushed them down and gave them in food without her knowing. She was confined to bed before she had the Tablets, and now is about again well and bright."

Mr. Inman is now in England, having had to return there some little time ago to take control of the well-known firm of A. W. Inman and Son, Printers and Publishers, Leeds. Letters will reach him there.

Dr. Cassell's Tablets

FREE SAMPLE.

On receipt of 5 cents to cover mailing and packing, a generous free sample will be sent at once. Address: Harold F. Ritchie & Co., Ltd., 10, McCaul-street, Toronto.

Dr. Cassell's Tablets are Nutritive, Restorative, Alterative, and Anti-Spasmodic, and the recognised remedy for

Nervous Breakdown	Sleeplessness	Mal-nutrition
Nerve Paralysis	Anæmia	Wasting Diseases
Infantile Weakness	Kidney Trouble	Palpitation
Neurasthenia	Dyspepsia	Vital Exhaustion

Specially valuable for nursing mothers and during the Critical Periods of life.

Sold by Druggists and Storekeepers throughout Canada. Prices: One tube, 50 cents; six tubes for the price of five. War tax, 2 cents per tube extra.

Sole Proprietors: Dr. Cassell's Co., Ltd., Manchester, Eng.

WAS TROUBLED WITH HER LIVER

FOR FIVE YEARS.

When the bowels become constipated the stomach gets out of order, the liver does not work properly, and then follows the violent sick headaches, the sourness of the stomach, belching of wind, heartburn, water brash, biliousness, etc.

Keep your bowels regular by using Milburn's Laxa-Liver Pills. They will clear away all the effete matter which collects in the system and thus do away with constipation and all its allied troubles.

Mrs. John Fitzgerald, Brittania Bay, Ont., writes: "I have been troubled with my stomach and liver for the past five years, and have had constipation causing headache, backache and dizzy spells, and sometimes I would almost fall down. I tried all kinds of remedies without obtaining any relief.

I commenced using Milburn's Laxa-Liver Pills, and they have cured me. I have recommended them to many of my friends, and they are all very much pleased with the results they have obtained from their use."

Milburn's Laxa-Liver Pills, 25c. a vial, 5 vials for $1.00, at all dealers, or mailed direct on receipt of price by THE T. MILBURN CO., LIMITED, Toronto, Ont.

stir rapidly for five minutes. Add the poison and apply to the vines.

Always test Bordeaux with litmus paper, which can be obtained from the druggist. Tear off a piece of the paper and dip it into the solution, if it turns the paper rel, add more lime until it turns the paper blue, which shows that the solution is alkaline and safe to be sprayel on the leaves.

Spray the potatoes for the first time when the plants are 4 to 6 inches high and repeat every ten days or two weeks, depending on the amount of rain. The more rain the oftener they need spray.

Spraying will fncrease the yield and make the potatoes keep. Buyers in large potato districts always discriminate in favour of the sprayed potatoes because they will keep and stand up on the way to market.

If you want 97 more bushels to the acre and potatoes that will not rot, you must spray them thoroughly. And if ever the country as well as the individual wanted such crops of potatoes it is in 1917.

Write to the Division of Botany, Central Experimental Farm, Ottawa, for Circular No. 10, on the Late Blight and Rot of Potatoes.

THE DANDELION PROBLEM

The dandelion so much lauded and sung by poets is the cause of some anxiety to more practical people. It is getting so common that some otherwise good lawns are a mass of the yellow bloom early in the season, which furnishes seeds enough to invade the province if left to be blown about. There is a laborious way of eradicating the dandelion, by grubbing it out with a small tool made for the purpose. There is such a tool with a long handle which may be used easily by those who dislike to stoop over too much. We have found that the dandelion pulls up very easily when the soil is wet, but it should never be thrown down, as even a fresh blossom will furnish vital seeds for germination wherever it chances to fall or to be blown. Burn all parts of the dandelion if extermination is the object.

Spraying the Dandelion

There is a spray which may be used successfully on this pest as well as on some others—chickweed, narrow dock, etc. A solution of sulphate of iron is destructive to these plants. Use a pound and a half of the sulphate of iron to a gallon of water and spray the infected places with this, using a sprayer that produces a very fine mist. It is best to make this application soon after the grass has been cut and when no rain is likely to come for a reasonable period of time. Surely this is well worth trying and re-trying on badly infested lawns and yards. The dandelion may be destroyed by cutting off just below the surface of the earth, so that the root gets no light whatever, or it may be destroyed by pouring gasoline or kerosene on the crowns, but with this individual treatment one might as well root them out and have it done with. If each person would keep them down on his own precints they would soon be under control if not entirely eradicated, and as soon as the young plants start the spray used in early spring agin would insure a clearance of the pest.

PROTECTION OF CROPS

(Continued from page 529)

nearest of the following sources of expert assistance: The Agricultural Colleges, the Provincial Departments of Agriculture or their local District Representatives, the officer in charge of the nearest Dominion Entomological Station, or direct to the Dominion Entomologist, Department of Agriculture, Ottawa, for examination; and advice in regard to control measures will be furnished without delay. Letters and packages up to 11 ounces in weight may be mailed to the Dominion Entomologist, "Free," but postage will be required on letters or specimens sent to the other sources of advice mentioned.

Do not delay reporting insect outbreaks or sending inquiries; delay may involve serious losses that could otherwise be prevented. Write immediately, or telegraph if the outbreak is serious. **Clean farming, the securing of vigorous growth in young plants and good cultivation are the best protective measures against insect attack.** Keep all crops constantly under supervision for the first appearance of any damage in order that it may be checked without delay. Increased crop production involves increased protection aganst pests.

FEED FOR PIGS AFTER WEANING

"Constant Reader," Sask., writes: "At present grain prices I find it a problem to keep down production costs. Immediately after weaning my pigs go backward. I would like to know what feeds could be given at that period to maintain normal growth. I have no milk for them, and would like to know the best substitutes for milk."

Reply by W. F. Stevens, live stock commissioner for Alberta:—

The substitute which is most nearly like milk and is available on most farms in Canada, is oats. These should be ground sufficiently coarse to permit the hulls to be screened out by means of a screen with about the same size of opening as ordinary mosquito netting. The meal which passes through the netting should be scalded from six to ten hours before feeding, and left to brew until required. When this has been cooled to a temperature of about 90 degrees, it forms a milky fluid, the solid portion of which is easily digested. This should not be fed cold to young animals, particularly during cold weather, because the shock is too great for the tender digestive organs of such animals, and because there is danger that as a result of this shock the glands which secrete the various digestive fluids, especially those of the stomach, will not act properly and indigestion will result therefrom. It is also important that the hulls of oats be separated from the meal and that these should not be fed to young pigs, because they set up an irritation in the digestive organs of animals of such tender age. It is advisable to continue separating the hulls from the meal which is fed to animals of this kind until they are at least three months of age. In pure-bred animals, especially those that are intended for show purposes, it is advisable to continue this practice for at least a month longer.

As regards concentrated foods that have proven to be good substitutes for skimmed milk, I might mention linseed meal and digester tankage. I hesitate, however, to recommend their use to inexperienced feeders, because unless handled very carefully and in moderate quantities their use is likely to be injurious rather than beneficial. When using foods of this kind in connection with moistened food, care must be exercised to see that all of the food supply is eaten up at once, because these foods ferment very rapidly and set up digestive disorders. They should not be mixed in with moist food until immediately before feeding.

I would not advise feeding more than two per cent of the grain allowance of either of these foods at the outset. They can be gradually increased to five per cent and beneficial results obtained, provided care is exercised in handling them. An over-supply of either of these foods is likely to set up digestive disorders from which the animal will be slow to recover. For these reasons I hesitate to recommend them to any but men whom I know to be experienced stockmen.

FARMING CO-OPERATION

Co-operative selling and buying requires no argument to-day to sustain its advantages. The saving in cost of handling large orders instead of numerous small ones is recognized by every business house. The wholesale houses do business on this basis, and are consequently able to sell their goods at much lower prices. The retailer has to break bulk, has many packages to weigh out and parcel up, has many accounts to make out and many orders to record. Over and above these costs is the very large item of delivery. This item is a serious matter in urban centres, but it is much more so in the country for, whether the dealer delivers them or the farmer drives in for his supplies, the cost is there.

In a recent rural survey by the Commission of Conservation, among 100 farmers in one township, it was found that 63 of them lived five miles or more from a shipping point. Of these 63 farmers, not one was either selling his produce or buying his supplies co-operatively. Each farmer was driv this ten miles (5 miles each way) to his market place, covering largely the same ground as his neighbours, using his tem and waggon, his own time and energy. In many instances the great waste of time and energy and the monetary loss due to the smaller business transactions might be materially reduced by extension of the co-operative system.

Earth or clay roads which were at one time impassable for wheel traffic on account of their muddy surface, have after being properly sub-drained, become most satisfactory highways, during all seasons of the year.

Don't Sacrifice Breeding Animals

Maintain and increase breeding herds.

Feed cheap roughages.

Feed live stock as little human food as possible.

Get Rid of the Blues!

A great many people are only half alive. Are you one of them? Exchange that down-and-out, what's-the-use feeling for the strength of better health, abundant nerve force, and keen relish for your meals.

One of Canada's most eminent physicians has expressed the opinion that the systematic keeping clear of the intestinal tract would save hundreds of thousands from that semi-insane state, melancholia.

For this purpose nothing can quite equal Chamberlain's Tablets. They also possess tonic properties which aid in establishing a natural and healthy action of the bowels.

THROUGH CAR SERVICE MONCTON TO LEVIS, VIA EDMUNDSTON—GOOD CONNECTION FOR FREDERICTON.

Summer Time Table Canadian Government Railways.

With the summer time table in effect Sunday, June 10th, passengers will be able to leave Moncton 4.00 p.m., Tuesday, Thursday and Saturday and travel in through car, via Edmundston to Levis, arriving there at 10.25 a. m. the following day. Returning the through ar will leave Levis Monday, Wednesday and Friday, 4.30 p.m., and arrive at Moncton at 12.05 noon, Tuesday, Thursday and Saturday.

By the same trains and on the same days from Moncton there is a good connection at McGivney for Fredericton, passengers arriving in the Capital City at 9.45 p.m. Returning passengers can leave Fredericton at 6.40 a.m. and arrive in Moncton at 12.05, noon, Tuesday, Thursday and Saturday—the quickest time between the two cities, Moncton and Fredericton.

Butter Parchment

Farmer Office

Sussex, N. B.

SHEARING AND DIPPING THE FARM FLOCK

(Continued from page 523)

do this after they have graded it into its proper grades.

In washing wool, I would like to know what is considered a fair shrinkage in the ordinary washing process. The shrinkage is figured at one-quarter, but I have found it much more than that. I have washed wool for others and when I have had it weighed before washing and after drying thoroughly, I have found the shrinkage to be one-third. I have washed wool in soft water and in hard water, and have used soap and soda, and have found no difference in the shrinkage. I have washed wool in a tub and have washed it in a barrel churn, and have found no difference in the shrinkage. I have washed wool in cold water and in warm water, and have found no difference in the shrinkage. I have washed wool in a tub and have washed it in a barrel churn, and have found no difference in the shrinkage.

Mr. Jennings has been a special graders for the Live Stock Division, Ottawa, while grading at Sussex recently he graded a number of fleeces for me. I sent him a pound sample of my wool, and he graded it as follows: Supposing that it was a fair sample of an eight pound fleece and that the prices were those ruling in Sussex on that day, washed 68 cents, unwashed 46 cents. 8 lbs. unwashed wool would be worth $3 68. An 8 pound fleece would shrink when washed to 5 pounds, which at 68 cents per pound would sell for $3.15, a difference of 53 cents in favor of the unwashed wool, to say nothing of the labor saving involved by not washing. Does this saving of labor and money appeal to you? If so, be in line to sell your wool unwashed and through a co-operative organization next year.

GROUND LIMESTONE

(Continued from page 527)

and mower rotation gave equally striking results. The only application of fertilizer in the rotation was made in the spring of 1914, it being a very light one consisting of 140 pounds nitrate of soda, 300 pounds acid phosphate and 100 pounds muriate of potash, per acre. On one series of plots, ground limestone at the rate of 4000 pounds per acre was applied in the spring of 1914. It was not to be expected that there would be much hay crop in 1916, as the plant food had all been used by the potato and the grain crop previously.

The following yields were obtained from the 1914 crop potatoes: unlimed, fertilized, 76 bus. 13 lbs. per acre; limed, fertilized, 86 bus. 45 lbs.

The yields for the 1915 crop oats, were: unlimed, fertilized, 31 bus. 24 lbs.; limed, fertilized, 38 bus. 14 lbs. per acre.

In 1916 the clover yields were: unlimed, fertilized, 675 lbs. per acre; limed, fertilized, 1483 lbs.

On one field of ten acres put down to clover in 1915, which was in corn in 1914, having been manured at the rate of 15 tons manure per acre for the corn, the gain from 1½ tons of ground limestone per acre, indicated an increase of fifteen tons on the ten acres over check plots left on the area unlimed. The limed areas yielded 5410 lbs. per acre, and the unlimed, 2400 lbs., a difference of 3010 lbs. per acre in favour of liming, or 15 tons clover hay at $10 per ton, $150. The fifteen tons of ground limestone cost approximately $6 per ton, or $90, leaving $60 or $4 per acre in favour of the limed soil

DUNLOP

Tire Mileage Achievements

SOME motorists think they have tires which are making great mileage records. Later these motorists meet users of Dunlop Tires. Then they get a *new conception* of what is possible in tire mileage.

"SPECIAL" TIRES "TRACTION"

METAL ROOFING FOR FARM BUILDINGS

The distinct advantages of Sheet Metal coverings for buildings of all classes has rapidly brought them to the fore during recent years, especially so because of the development of mechanical appliances to perfect the manufacture of various types of Metal Shingles, Siding, Etc. Formerly, however, the wood shingle was the most popular on account of its cheapness and handiness. Many buildings were covered with wood shingles, and labor-saving machinery was used to manufacture the shingles by sawing them from blocks of wood. There are yet many districts in the Country where split or shaved cedar shingles were applied forty years ago. These shingles were generally about four inches thick and the sun and weather have reduced the thickness of the exposed portion of these shingles to that of cardboard. Under the natural tendency of things, however, the days of split or shaved cedar shingles are passed and in recent years and toward the latter quarter of the 19th century, shingles became the product of the saw mill, and manufacturers of shingles were not very particular as to the kind of stock they used and employed butts and all kinds of sappy stock, and the outcome of all this was that the shingles were put on the market at a price that commanded trade, but gave little satisfaction. The far-seeing farmer, however, when he could afford it employed steel and it was a common thing and is becoming a universal practice to use metal in some form for covering their buildings.

Until recent years a galvanized iron roof was a luxury, but the introductions of modern machinery has reduced the cost of galvanizing to a minimum, and through the perfection of up-to-date machinery many safe and prosperous firms in Canada have been able to put on the market a very substantial and practically everlasting roof in the form of Metal Shingles at a very moderate cost.

The great feature about the Metal Shingle and Roofing is that it does not take an expert workman to apply it. Any unskilled buyer with a moderate degree of adaptability, a pair of snips and a hamer, can apply these up-to-date shingles and Roofings and Sidings.

The greatest Virtue of the Metal covering and one recognized by Insurance Companies is that the risk from fire and lightning is minimized by the use of metal roofing. They now offer the farmers special inducements in the way of reduced premiums to encourage the use of galvanized iron covering. The people themselves recognizing the opinion of the best authorities soon found that a building covered with an iron roof, which roof was properly connected to the ground by a water-spout or even a wire contact, was absolutely proof against a lightning bolt. They also recognized that burning embers from another fire lighting on a metal roof did no damage whatever, and all these factors lead to a larger consumption and use of metal roofing to such an extent that the wooden shingle fire hazard is being steadily eliminated.

Another important factor in favor of the Metal Shingle and Roofing is the weight. Wooden Shingles would average about 250 lbs. to the 100 sq. ft. Slate would average about 600 lbs. whereas a first class Metal Roof will not average 100 lbs. thereby lessening the needed strength of the superstructure and trusses. Likewise, it has been proved beyond any shadow of doubt that heavy and wet snow will not remain on sloping metal roofs whereas it will attach itself to wood averages sometimes 50 lbs. to the square foot.

The Metal Shingle of to-day is the last word in roof covering, it is rain-proof, fire-proof, lightning-proof, frost-proof; all nails used to apply a metal shingle roof are covered up with the succeeding sheet, which prevents the snow and frost from causing any disturbance, the sheets are fitted with locks which give ample room for contraction and expansion, and metal shingles are giving the same degree of satisfaction to-day, as they did when applied nearly thirty years ago. In addition to the metal shingle there are various other types of metal roofing such as corrugated iron, V crimp and roll roofings, all of which give ended protection to the building on which they are applied.

When speaking of durability of a metal roof, galvanized materials only are referred to. Farmers in this country nearly twenty years ago applied painted Roofing, and the repainting of this roofing, which in some cases should have been an annual affair, was neglected, and the consequence was that corrosion set in and their roofs rapidly deteriorated, but this is not the case with Galvanized Roofing.

In the Rural Municipalities, where sulpharous acid gases are not prevalent, a Galvanized Roof made of good material and properly applied should give satisfaction for half a century at least, in fact, it will give satisfaction—the test of time has proven so.

In the march of progress, many of the up-to-date farmers recognizing the superior qualities of metal over wood are now adopting as a safeguard against fire, lightning and decay many forms of sheet metal products such as metal roofings, sidings, ventilators, silo covers, etc., thus reducing risk as well as maintenance cost.

FIRST AID IN ACCIDENT CASES IN FARM HOMES

In every home there should be kept, where it can be readily found in case of accident, a box containing various simple remedies and other articles likely to be needed, if one of the family should be injured and the physician delayed, or if the injury should be so slight that the expense of a physician may be unnecessary if the patient receives intelligent and prompt attention.

In the "emergency box" should be kept a supply of bandages of different sizes and widths, and bundles of absorbent cotton, large squares of soft old linen, and a collection of worn-out linen handkerchiefs. The bandages may be bought in a large box from a druggist or the family physician, or they may be made at home. If they are to be made, everything about the work must be absolutely clean, or there is danger of infection. Tear into lengths an old sheet, having the strips from two to four inches wide. Pull out all the threads that ravel from the edges, and then roll tightly into little rolls, and fasten the ends. These should be kept in a small box or in a large mouthed glass jar.

Arnica, witch-hazel, some true and tried liniment and as good a corn-cure should be kept in the box; also a jar of cold-cream, another of vaseline, a package of bicarbonate of soda (for slight burns), a bottle of olive-oil (to use with the soda), and such toothache remedies as seem efficacious. Of these, spirits of camphor or oil of cloves mixed with an equal quantity of either or chloroform are perhaps as good as any. A pair of small chop-bags, made from empty salt-bags filled with the hops that can be purchased by the package, are excellent for an attack of neuralgia. These should be kept in one of the

FLEET FOOT

ATHLETE BAL

the entire contents of the larger box.

Salt-bags are also good for pain, and are made by half filling two small-size bags with salt. These bags are to be placed in the oven on a pan, and heated alternately, then applied to the seat of the pain. Pieces of flannel that can be wrung out of hot water should also be kept in the box, where they may be found at once if the small boy of the family has been indulging in green apples or other forbidden fruit, or for colic to which many adults are subject.

The coarse salt-bags are also useful for making poultices on for filling with cracked ice if an ice pack is prescribed. The bags should be washed out as soon as they are empty, and put carefully away in a small box.

In a glass fruit-jar should be kept flaxseed, and in another hop-leaves, for use in making poultices when required.

Always spread a poultice with vaseline before applying it, so that it will not blister the skin.

No home should be without a remedy for burns, but a burn that is at all serious should at once receive the attention of a physician. For slight burns a bottle of collodion is best of all, for it forms a coating over the wound, which keeps out the air. It is the air striking on the burnt place that makes it smart. If the other until the burn is well covered from the air will allay the pain. Collodion is inflammable, and will evaporate if allowed to remain uncorked.

For really serious burns the following ointment is to be recommended: Pound one ounce of gum camphor in a mortar until it is reduced to a powder, then mix thoroughly with two tablespoonfuls of fresh lard until it forms a salve; turn it into a glass or porcelain ointment-jar, and keep tightly covered. This salve is said to prevent scars if applied immediately after the accident occurs. If one is far from a physician, and there is doubt about securing his services at once, apply the salve freely to the wound and to the surrounding surface of the skin, and then cover closely with cotton wool. If there is nothing better at hand, mix carbonate of soda with olive-oil, spread on cloths, which should be saturated with it, and gently press over the burn; then wrap in cotton wool, to exclude the air, and await the arrival of the physician.

For slight hoarseness and cold on the chest give vaseline mixed with sugar, and rub the chest with turpentine and vaseline of turpentine and lard. If the children come home from school with symptoms of an oncoming cold give them six or eight drops of

Kingshurst, Farm, Rothesay, Kings Co., N. B.

NOTICE

The attention of owners of stallions is drawn to "An Act to Provide for the Inspection and Registration of Stallions," 5th George V., Cap. 18, and 6th George V., Cap. 44, under which all stallions travelled or offered for service must be enrolled at the Department of Agriculture on or before the 1st day of May, 1917.

Inspectors will be appointed by the Department, to report on each animal before a certificate is issued. Evidence of breeding and ownership must be submitted and a fee of $2.00 forwarded with application.

Further information can be obtained by applying to

Department of Agriculture
Fredericton, N. B.

In the list of semi official Records of Holstein Truesiam cows completing yearly records from April 1st to April 30th, 1917 we find the following cows in the mature class:—

Iosco Posch, 9683 aged 7 years, owned by D. R. Nicholson, Coxheath, N. S. with a record of 14848 lbs milk yielding 402 lbs. fat the equivalent of 502.5 lbs butter 80 p. c. fat and Jacoba Emily Drkol, 11071, aged 7 years, owned by J. H. Stockton, Woodstock, N. B. record 13.502 lbs milk, 432 lbs. fat, the equivalent of 540 lbs butter 80 p. c. fat.

A BOUNTY TO CROP PRODUCERS

To any farming community within this province which desires it independence of foreing supplies of Clover Seed, the New Brunswicw Department of Agriculture offers the use of a clover-thresher.

This machine was operated in Carleton County last year, where it threshed approximately three hundred bushels of Red Clover Seed.

The charges for threshing include only the cost of operating during the actual running time of the machine, which, last year was one dollar and thirty-seven cents per hour.

The capacity of the machine is two tons of clover hay per hour, yielding approximately seventy-five to ninety pounds per ton.

The Department provides two men to operate the outfit; all extra help required is to be supplied by the person for whom the threshing is done.

Terms and Conditions

1. Any Agricultural Society or group of five or more farmers having a minimum of ten acres of clover intended for threshing, may apply for the threshing outfit.

2. An application from the Agricultural Society must be signed by the president and secretary.

3. An application from a group must be signed by at least five bona fide farmers, having clover for threshing aggregating ten acres or more, who shall appoint one of their number to make the necessary arrangements with the Department of Agriculture.

4. Applicants must agree to the following conditions:—

(a) To have the clover crop cut and in condition for threshing. This will in most instances necessitate storing the crop.

(b) To provide transportation of the threshing outfit to and from the nearest railway centre.

(c) To transport to the machine the material to be threshed and remove the straw when necessary, as the operator shall direct, and to transport any gasoline or water required for the engine.

Time for Harvesting

Seed formation of common Red Clover in the early stages of growth can be readily observed by cutting the flower heads, lengthwise and to one side with a sharp knife. The seed bearing heads later become plump and brown, and may be detected if squeezed between the thumb and finger, or they may be shelled out in the hand. When observed in any large proportion of flower heads, a profitable seed crop is assured whether occuring in first or second crop.

Cutting should not commence until the seeds are quite firm and well colored; (which corresponds to the late dough stage in corn.)

Harvesting the seed crop is accomplished by cutting with a mower when the growth is excessively heavy, or by a self-rake reaper, or even a binder, with or without the trying apparatus, but perferable without. A table attachment, or buncher, is made by some farm machinery companies, attachable to their mowing machines, which work well where the crop is not heavy.

About ten days are required to properly cure the crop. The bunches should be frequently turned to assist the drying, and the crop should be stored in a dry mow.

Clover is well termed "The corner stone of Agriculture," for without it there can be no permanency to our type of farming. It acts as the miller and baker for other crops and is indispensable to a permanent agriculture.

All inquiries for further particulars relating to the production or threshing of Clover Seed, will receive attention by applying to the Secretary of the Department of Agriculture, Fredericton, N. B.

A can of mustard should find a place in the emergency box, as well as court-plaster and plasters of other kinds.

R. O. P. HOLSTEINS !

Two Bulls fit for service, sired by the "Champion" Holstein Bull of the Maritime Provinces. Dam of one gave over 11,000 milk and 500 butter in a year at 2 years old and the other is full brother to a 4-year-old show cow that made 468 lbs. milk and 20 lbs. butter in a week in R. O. M. and is now finishing a R. O. P. yearly record of over 16,000 milk and 700 butter at 4 years old. For full information and price write

No Permanent Road Without Good Drainage and Sound Foundation

Spend Money on These and the Surface Will Look After Itself.

Address by Geo. Hogarth, O.L.S., A.M., Can, Soc. C.E., Before the Dominion Good Roads Congress

In building any roadway whether for light or heavy traffic two of the most important points to be considered are drainage and foundations.

The stability of the entire road surface depends upon the foundations and the strength and life of the foundation largely depends upon the facilities provided for drainage. While proper attention may be given to the drainage of the surface of the road by giving the roadway sufficient crown to shed the water, the great importance of subsurface drainage may be entirely overlooked. There are, therefore, surface methods of drainage and subsurface methods of drainage and the importance of each must be realized and used to the fullest extent if we desire a permanent foundation. A sound and enduring foundation cannot be secured on subsoil saturated with water, but a good foundation can be secured by the simple means of keeping the subsoil dry. If water is not excluded from the foundation it will sooner or later destroy the road surfacing, since no road ever built could escape destruction should the foundation become yielding and soft.

The ordinary clays and earths form a naturally strong foundation when dry, but where the ground is wet and springy a good road cannot be constructed without proper subdrainage since when wet, the earth loses its sustaining power and the surface formation goes to pieces. Where the subsoil is gravelly, underdrains will usually not be required, but where it is sandy, give close attention to the damp or wet spots and provide ample subdrainage.

It may be said that the whole problem of provement and maintenance of ordinary country roads is one of drainage. Upon earth roads drainage is especially important because the material of the road surface is very susceptible to the action of water and so, more readily destroyed than are the surfaces of the better class of roads. An undrained earth road offers a splendid opportunity to the frost, and a spring thaw may result in such a road being impassable for days and weeks. A road on a wet undrained bottom will always be troublesome and expensive to maintain and it will be economical in the long run to go to considerable expense in making the drainage of the subsoil as perfect as possible.

There are three systems of drainage namely; underdrainage, side ditches, and surface drainage and the objects of each will be stated:

Underdrainage will lower the water level in the soil and keep it at a safe distance from the foundations. This aids the action of the sun and wind, which tends to dry the surface of the road, but if the foundation due to lack of underdrainage, is soft and spongy, the road will soon become a mass of mud.

Underdrainage dries the ground quickly during the spring when otherwise a saturated condition of the soil would exist.

Underdrainage intercepts the subsurface flow of water beneath the crust of the road.

In many cases it will be noticed that though the ground is dry when it freezes in the fall, it is very wet and boggy in the spring when the frost comes out. The reason for this condition is that after the ground freezes, water rises slowly in the soil and if it is not drawn off by underdrainage it saturates the subsoil and rises further as the frost goes out. Underdrainage not only removes the water but reduces and will in many cases prevent the destructive heaving effects of frost.

The heaving and cracking of pavements may be entirely attributed to the freezing of water in the subgrade under the pavement. Underdrainage will greatly lessen the damage done in this way by the frost but to entirely prevent such destructive action may be very difficult. It may be said that when underdraining a section of road known to have a wet subgrade it is well to provide a liberal number of drains. Too many cannot be laid. Particular attention to the underdrainage should be given at points on the road from 50 to 200 feet or more down grade from the top of the hill or slope and particularly so if the roadway is in excavation. Water will usually filter out to the surface at such points and the entire skill of the roadbuilder will have to be exercised in locating subdrainage to prevent heaving and cracking. In all such cases do not curtail the underdrainage but rather put in every foot of tile that can be placed.

Wherever underdrainage is provided be careful to provide proper grade and good outlet for the tile since poor results will come from tile that are indifferently laid and improperly vented.

Tile drains furnish the usual means for subdrainage, but in some cases a blind drain may be used to good advantage. The construction of a blind drain is accomplished by opening a trench several feet deep along or across the road and afterwards filling the trench with stone. The depth, distance apart, and location of such trenches will depend entirely upon the conditions encountered and the result desired.

Careful attention to the subdrainage of the road is of great importance and money spent for such work is always a splendid investment.

Side ditches for all country roads are essential. Their object is to receive the water from the surface of the travelled roadway and the grade of the ditch should be such that the water is carried rapidly to a good outlet. Such ditches also intercept and carry away water that would otherwise flow from the side hills upon the road. Side ditches need not be very deep, a depth of 2½ or 3½ feet below the crown of the roadways will usually be found sufficient and the sides should be given a slope flat enough to prevent caving. In order to be effective, ditches should have as great a grade as possible, they should be well cleaned out and have free outlet in some creek or stream.

Surface drainage of the traveled portion of the road affects mainly the maintenance of the road and is accomplished by giving the road or pavement surface a crown whic htends to shed the water to the side ditches. The slope of the crown should be sufficient to carry the water freely and quickly to the side ditch. The proper crown to use will vary with the nature of the roadway; when a good surface is maintained a moderate rise will be found sufficient. For earth, clay or gravel roads a usual crown is one inch per foot while for bituminous or concrete pavements ½ or ¼ of an inch per foot is ample.

FOUNDATIONS

While drainage is undoubtedly one of the first essentials of good highways, the foundation of a road is also of great importance and one of the first substantial advances in road building was made when the laying of a course of stone for the base of a road was adopted.

The foundation of a road should normally last a number of years while the cost of maintenance should be for replacing and renewing the worn out surface. Such conditions are difficult to obtain since the foundation of 4 inches of crushed stone today may be entirely inadequate, tomorrow under more severe traffic. The heavy loads using our highways today require an abundance of material in the foundation of the roads and if our work is to be enduring we must see to it that strong and sound foundations are provided.

Frequently the taxpayer may enquire as to why so much material is required in a road and a demand will be made for more surface with a smaller amount of stone hidden in the foundation. Such an enquiry loses weight when the same ratepayer states that a concrete road 6 inches thick is too heavy and his idea of a concrete road is a surface of concrete about an inch thick spread over the entire space between the fences.

Roads built only a few years ago are in many cases in poor condition or destroyed today because a shallow, weak foundation was provided. Improved roads naturally draw traffic and people will go miles out of their way in order to travel over a section of good road. This fact should be given full consideration in designing a road and any traffic census made prior to reconstruction should be considerably increased in order to estimate the travel on the improved surface. A road is not rebuilt to provide only for present traffic but it is rebuilt to carry present traffic together with whatever vehicles may use it when improved and in some cases it may be found that the traffic on an improved road immediately after reconstruction is ten or more times the original number of vehicles using the road.

The strength of the faundation of a road is greatly affected by the supporting power of the different soils and in order to obtain a road surface having a uniform resistance the thickness of the crust will need to be varied. A greater depth of foundation will be required on clay than on gravel, and for soils of intermediate strength a varying thickness will be required. Soils of poor supporting power will carry safely a load of about 600 pounds per square foot, while gravel subsoil is safe under a loading of about 3,'00 pounds per square foot.

Many kinds of foundation courses are available in the construction of roads, such as: Crushed stone, screened gravel, pit gravel, field stone, quarry stone of Telford. Before placing a foundation course the subgrade should be properly rolled in order to solidify the surface and prevent the material of the foundation being forced into the soil. This point is as important with a gravel road as it is with more permanent types of construction. A smaller amount of crushed stone or gravel will be required to build the foundation of a road on a consolidated

SWEET CLOVER---THE TRUTH

By M. O. Malte, Ph. D.

During the last twelve months or so the interest in Sweet Clover, shown by farmers in different parts of Canada, has assumed surprising proportions. Numerous articles in the agricultural press and still more numerous 'letters to the editors' of the agricultural papers have discussed the sweet clover question, but so far no definite conclusions as to the merits or demerits of the sweet clover have been arrived at.

A certain number of the writers cannot condemn it strongly enough claiming that it is a 'nuisance' and a 'pest' which when introduced on a farm will spread beyond control and which will lessen the value of the farms. Instances have been quoted, in which the selling price of farms has dropped as much as two thousand dollars on account of their being overrun by sweet clover, wilfully introduced by their owners.

On the other hand a great number of writers are enthusiasts who look upon sweet clover as a forage crop of extraordinary value which, unfortunately, has been misjudged and altogether underestimated in Canada. Articles have appeared in which the writers remark that "colleges across the border are loud in its praise' and that it is a 'staple crop in Europe,' etc.

The result of these contradictory statements is that the unfortunate farmer who is unfamiliar with the plant in question is at a loss as to its real value.

In the following paragraphs a few facts will be given which, it is hoped, will help to clear the situation.

Varieties

Under the name of Sweet clover are recognized a number of leguminous plants characterized by a very pronounced sweet odour. They all belong to the same genus, viz: Melilotus, and are often called melilots. Although called sweet clover, they have not much in common with the true clovers, represented by the Red, White and Alsike varities. As a matter of fact, they are more related to alfalfa than to any other leguminous plant.

There are two varieties of sweet clover in Canada, the white and the yellow. The former (Melilotus alba) is the more common and is considered somewhat superior to the latter (Melilotus officinalis). Both these sweet clovers are biennial, i.e. live two years.

A third variety, called Melilotus indica, is a small annual plant, which is grown in California, Utah and other western states of the Union.

In Canada, only the White Sweet Clover is of any agricultural interest.

Origin and Distribution of White Sweet Clover.

White Sweet Clover, also called Bokhara Clover, is a native of Asia. It was introduced into Europe over two thousand years ago and was brought to America about the middle of the eighteenth century. In Canada it is now found quite commonly, especially in the eastern provinces.

Requirements as to Soil.

Sweet clover can be grown successfully on almost any kind of soil. It is often found in sterile, dry places where nothing else will grow on account of lack of food. It will thrive surprisingly well in sandy fields, on stiff clay, in sour soil, on alkali land and in many other places where most farm crops prove a failure. This ability to live and, in fact, to do well in soil where the food supply is scant, is largely responsible for the glowing praise bestowed upon sweet clover during recent years.

Sweet Clover as a Soil Improver

Like most other biennial plants, sweet clover develcps a strong and somewhat fleshy tap root which penetrates the ground to a considerable depth. Its numerous branches break through even very compact soil, thus makiny it porous and penetrable to air and water. The fleshy nature of the taproots makes them decay readily when the plants, after the end of the second year, die. Considerable humus can also be added to the soil by incorporatinp with it the rathor rank top growth.

For these reasons Sweet Clover is no doubt of great value on old, worn-out land and on soil the mechanical condition of which needs improfing.

Like other leguminous plants Sweet Clover through the assistance of certain bacteria has the faculty of gathering nitrogen from the air circulating in the soil. Soil deficient in nitrogen will consequently be improved through the growing of Sweet clover.

In this connection it must be mentioned that the bacteria occurring on the roots of Sweet clovor, seem to be identical with those occurring on the roots of alfalfa. At any rate, they act in exactly the same way as the alfalfa bacteria, and soil from a sweet clover field can therefore be used to advantage for inoculation of fields prepared for alfalfa. For the same reason, sweet clover can be used, on poor soil, as a preparatory crop for alfalfa.

Attractiveness to Stock

One of the most serious objections raised against sweet clover is the statement that farm anmals do not like it and that they cannot be induced to eat it unless starved. Its distastefulness to stock is, as is well known, due o the presence of a bitter element, called cumarin, which is especially noticeable in the wild plants.

On the other hand, it has been claimed that animals are very fond of it and prefer it to other kinds of fodder.

Observations made by the writer indicate that cattle and horses at least carefully avoid sweet clover in pastures, where other plants are at hand, and that, to most animals, the hay is far from attractive. But domestic animals, like human beings, can develop a taste for and grow very fond of food which they at first refuse to touch. Whether animals, unfamiliar with sweet clover, will like it or not from the beginning also depends upon what time of the year they be pastured on it. If turned on to it early in the spring when the plants are very juicy and tender, they will have less objection to it than later when the plants are better developed. This is due not only to the fact that early in the spring the animals are hungry for green feed, but also because that the young plants contain a much smaller amount of cumarin than the older ones and consequently are less bitter.

Sweet Clover for Hay and Pasture

As a hay crop, sweet clover cannot compete with alfalfa. Full crops can be relied upon only every second year, whereas a well-establishes alfalfa field will yield large crops during many consecutive years. In feeding value it is also inferior to alfalfa, holding less protein and less carbonhydrates than the latter. Where alfalfa can be grown with reasonable success, sweet clover should, therefore, by no means be introduced.

The principal advantage of sweet clover for pasture lies in its ability to shoot very early in the spring, to remain green during periods of prolonged drought, to continue growth until late in the fall, and to stand close grazing well. As a rule there is no danger of sweet clover producing bloating. But even with all these good qualities it is doubtful whether it will ever be of general importance as a pasture crop in any part of Canada. It will be useful only on soils too poor for other pastures.

The statement sometimes made that, in Europe, sweet clover has been cultivated for hundreds of years as a staple crop for hay and pasture, has no foundation whatever. As a matter of fact, it is, in Europe, generally looked upon as a weed pure and simple.

Objections to Sweet Clover

Apart from what already has been said against sweet clover, there are a few other objections of a more serious nature, which should be given due and careful consideration by farmers before they decide to introduce sweet clover as a farm crop.

Character of the Weed.

It is often claimed that sweet clover, on account of being a biennial plant, cannot assume the character of a weed, if properly handled. Being a biennial it lives only two years and if the plants are prevented from going to seed the second year, there should be no danger of sweet clover spreading all over the farm.

Theoretically this is perfectly correct and sounds well, but in practice it turns out to be quite different.

The writer goes so far as to say that sweet clover, when once introduced on a farm, will prove almost impossible to get rid of, no matter what precaution be taken. Many a farmer, believing that he had destroyed every sweet clover plant on his farm before it had had any chance to set seeds, has been painfully surprised to discover that, in spite of all, sweet clover suddenly appeared in the most unexpected places. In practice even the most careful eradicative methods and the most careful effort to prevent it from going to seed have too often proven in vain. Over and over again it has been discovered that seed, in spite of the most careful attention, has been developed and dropped to the ground. Only a few such overlooked seed will be sufficient to start a weed crop which very soon will prove detrimental to a well managed farm.

Even granting that sweet clover may be checked or quite suppressed in well cultivated and clean-kept fields, there are always places on a farm where sweet clover, once introduced, is apt to take a firm foothold. Along roadsides, fences, ditches, etc., where it is not properly looked after, it will have an ample opportunity to produce an abundance of seed which, by wind and water, will be carried over the farm and rapidly infest whole districts.

Menace to Alfalfa-Seed Producing Districts

On worn-out soils or in districts where absolutely no other leguminous forage crop can be raised, the nuisance character of sweet clover may be counterbalanced by its good qualities. But in good or even medium agricultural districts, where clean farms and clean seed are essential to the success of farming, the weed characters of sweet clover make it utterly objectionable.

This is especially the case in those districts of Canada where alfalfa seed raising looks promising or has already proven a succes.

The young sweet clover plant is very much like the young alfalfa plant and the average farmer will not be able to tell the difference. When the plants have developed blossoms the difference first becomes noticeable. In alfalfa seed growing districts where sweet clover grows as a weed in waste places and similar localities, the farmers lways run the risk of having their seed field infested with the same, the result being, of course, that the alfalfa seed, harvested from the infested field, will contain more or less sweet clover seed.

The seed of sweet clover is very similar to alfalfa seed, in fact so similar to it in general appearance that even experienced seed analysts often fail to detect it when mixed with alfalfa. This being the case, the alfalfa seed growers, maybe unknowingly, may put on the market alfalfa seed contaminated with sweet clover. That 'accidents' of this kind most necessarily will hurt the reputation of the whole seed growing district and the alfalfa seed industry of Canada in general needs no special explanation.

The danger of getting alfalfa fields infested with sweet clover is especially grave in irrigated districts. It will grow abundantly and luxuriantly along the irrigation ditches, and produce large quantities of seed which will be dropped into the ditches and carried by the water all over the irrigated area. This rapid spreading through the irrigating waters has caused a number of the irrigated States in the American west to look upon sweet clover as a troublesome weed.

ALFALFA TIPS

Plan to do everything quick when you work with alfalfa.

Cutting should commence when 10 per cent. of the plants are in bloom. As soon as the green sprouts begin to show at the roots of the alfalfa there is nothing to be gained by leaving it stand any longer.

Under no condition should alfalfa be raked, bunched or stored while it is wet with dew or rain. If this is done it is liable to heat.

Cut alfalfa on a day that promises to be fair. Set the mower bar so that it will cut high enough to not injure the young shoots. If rain prevents the cutting of the crop until the shoots are longer, set the cutting bar higher still. Clipping off these fresh growths delays the development of the following crop.

In harvesting alfalfa three things should be remembered: First, that its feeding value is greatest if cut just after blooming has commenced; second, that the leaves which fall oc with the slightest provocation when dry contain by far the most valuable part of the crop, and third, that rains not only discolor the crop and make it less palatable and less digestible but also remove in solution much of the nutritious part of the fodder.

In order to save the greatest part of the leaves the curing of alfalfa in cocks is recommended. It takes more time but makes far better hay. Rake shortly after cutting and bunch immediately. It may be necessary to turn the bunches out a few hours before stacking to let the lower layer next the ground dry out. Do not make the bunches too big; they may mould and heat.

The curing process that goes on after the alfalfa is cut is quite remarkable. Neither the leaves nor the stems are dead. The life processes of the plant continue and the moisture moves up the stem to the leaves, resulting in a uniform drying of the hay. The leaves act as pumps in their dying attempts to secure more moisture.

When hay has been stored in the mow or the stack after being thoroughly cured in the cock it will retain its bright green color. If it is stored a little on the green side, while the stems still contain a considerable amount of plant juice, heating and fermentation occur in the stack and a very aromatic and palatable brown hay results. It should not, however, be stored so green that it will heat or mould.

THE FEEDING OF SWINE

By G. B. Ruthwell, B.S.A., Assistant Animal Husbandman

Anticipating the needs of the near future with regard to meat of all classes, it is apparent that the relation of supply and demand will be such as to make imperative, heavily increased production. That this increased supply should be of a rapidly available nature is peculiarly desirable under the conditions that apply to the nation at war. In this connection swine may be bred, fed and marketed with greater despatch and in greater numbers than any other farm animal now contributing to the great meat-markets. Heavy home consumption and tremendously increased export trade make a permanently profitable market certain, if the opportunity is realized and grasped.

To the farmer, who with profit to himself and country wishes to accelerate his endeavour in solving one of the nation's war-time problems, the following pages may prove of interest.

Feeding and Management

In the consideration of feeds for the production of cheap pork, choice is largely influenced by locality, season and local conditions. By these factors economy of purchase or production is governed, provided the food is palatable, easily digested and nutritious—essentials in any successful ration. The complete ration must, further, be properly balenced, compounded of a variety rather than one or two constituents, and above all things contain some succulent food, winter or summer. On the latter or natural class of food, largely depends the continued health of swine. It is essential in the feeding of breeding stock.

The Stock Boar

Summer Feeding.—Supply a pasture of clover, alfalfa, or fine grass with water and shade. If no pasture is available, supply fresh green food liberally—clover, alfalfa grass, green peas and oats or weeds, as lamb's quarter, pig weed, dock, etc.

Winter Feeding.—Alfalfa or clover hay fed dry, in racks. Roots, such as raw mangels or sugar beets, pulped; cooked potatoes and turnips, 5 to 10 pounds daily; or in the absence of roots, clover or alfalfa hay, cut fine and soaked or steeped.

Feeding the Year Round.—If skim-milk, buttermilk or whey are available, supply at rate of 3 to 10 pounds daily as needed. The meal ration may be made up of ground oats, ground barley, bran and shorts in any combination of two or more, fed at the rate of 2 to 5 pounds per day, as needed. Use judgment in feeding the boar. If over-fat, he will prove a poor or uncertain stock-getter, indifferent and sluggish at service. If he is too thin, he will transmit to his get, lack of vigour and vitality and poor condition generally.

Exercise.—Importance cannot be overestimated. Supply a roomy shady pasture in summer, not a filthy, fly-infested pen or corner. In winter, arrange a paddock out-of-doors, close to the barnyard. If convenient give him the run of the yard for a few hours daily. As a shelter use, the year round, a cheap, portable, single-boarded cabin about 6 feet by 8 feet. Supply plenty of bedding. By feeding and caring for, as outlined, crippling and rheumatism, so common in boars, will be avoided.

The Brood Sow.

Summer.—Pasture, same as advised for boars.

Winter.—Roughage same as for boars. Meal mixture of bran two parts, shorts, one part, except when nearing farrowing-time, when the mixture should be of equal parts. If necessary ground barley or oats might replace either. Avoid corn in more than one-quarter the ration. For the breeding sow it is debilitating and over-fattening. Feed meal at the rate of 2 to 4 pounds as needed.

During Gestation.—Flush, or bring the sow into good condition before breeding. Maintain this condition after breeding. Avoid over-fatness with the ensuing troubles—difficult farrowing, small, weak, or dead pigs. Too thin condition, particularly with a young sow may permanently injure, in any case will likely mean small, thin pigs, a high percentage of runts, and small milk secretion. The in-pig sow must receive a cooling ration tending toward a laxative nature. The ration above advised qualifies in this regard. Remember first and last, that constipation at this time makes very certain, serious trouble with the litter—small, unthrifty, poor-doing pigs, due to constipation in both themselves and their mother. Such litters dwindle rapidly with no perceptible cause.

Exercise.—Equally as important as with the boar. With the exception of that period spent in the farrowing-pen, house the brood sow outdoors the year round in a portable cabin, 8 feet by 10 feet, and as described, placing four or five sows in each cabin. Choose a dry site. Make the sow work to obtain feed. This has an unfailing influence on the vigour, size and numbers of the coming litter, and lessens liability to rheumatism and crippling.

After Farrowing.—Avoid exciting the sow during or after farrowing. Always be present at this time, but give only such attention as may be required; no more. The first feed should be a tepid slop of middlings. During the first ten days gradually increase ration to maximum. Particularly avoid overfeeding, causing scours and thumps in little pigs. Feed the sow for milk production such rations as ground oats, middlings (equal parts), or ground oats, bran shorts (equal parts), both combinations with milk products. In summer allow green feed or pasture only after pigs are two weeks old. In winter, feed roots, clover hay, etc., to keep the bodily functions healthy and blood cool. Empty a pailful of earth and wood ashes in a corner of the pen. When weaning cut down meal supply and remove young pigs for longer periods each day until the sow is dry. If pigs are over-fat lazy and sluggish and the sow a heavy milker, force exercise.

Weaning Pigs

The strength of the pig when farrowed (governed largely by factors already discussed) exerts possibly the greatest effect on the ultimate economy of production. Second only to this point in importance is he influence of wisdom in the feeding and management of the sucking and the weaned pig. More good litters are ruined—and more swine-feeders baffled and discouraged—by improper feeds and feeding and ill-advised methods at the period mentioned, than possibly during any other phase of the pig's existence.

Teach the litter to eat three weeks before weaning. Use a creep which admits the pigs but not the sow. For bst results milk products are practically a necessity, with middlings. A few handfuls of dry grain scattered in the bedding ensures the pigs taking exercise. Avoid overfeeding, and make exercise necessary. Gradually increase middlings until weaning. If skim-milk is avaflable, and two litters per year are anticipated, wean at six weeks of age; otherwise, wean at eight weeks.

Ration for Weaned Pigs—After weaning start grain feeding as follows: Daily ration for the two or three month pig weighing about fifty pounds; 1 pound of a mixture of barley, 3 parts; shorts, 3 parts; linseed oil meal, 1 part; with 5 pounds of skim-milk daily. Soak for twenty-four hours, and feed. If in pen, add to this some dry grain, oats or corn, scattered in litter. This is not necessary if pigs are on grass paddock. As pigs increase in age, gradually increase the grain to three pounds or more daily, as needed, increasing also the proportion of ground barley or oats in the mixture, until at six months of age the ration consists of ground corn or barley, 6 parts; shorts, 3 parts; linseed oil meal, 1 part. Shelter the pasture or paddock-fed pig either with a portable cabin or a light open-sided shed. Avoid, particularly, turning the weaned pig outdoors to a shadeless paddock. Sunburn, skin trouble, temporary and often permanent stunting, ensues. Have natural shade if possible and supply clean, fresh water.

Other Good Growing Rations.

1. Ground barley, 4 parts; shorts, 4 parts; gluten feed, 2 parts; skim-milk, 3 pounds.

2. Ground oats or barley, 4 parts; shorts, 4 parts; ground peas, 2 parts; skim-milk, 3 pounds.

3. Ground wheat or shorts, 2 parts; barley, 2 parts; ground peas, 1 part; skim-milk, 3 pounds.

Numbers 1 and 2 would be applicable to Central and Maritime conditions, while No. 3 would be more adapted to Western needs.

Pastures

Compared to pen feeding, the pasture affords 5 to 25 per cent cheaper gains. For growing breeding stock, pasture feeding provides for growth of bone and muscle and general vigorous health. For fattening and finishing pigs, firmer, better quality pork will result. With the latter class of stock, however, the range must, of necessity, be more limited. Alfalfa forms the best pasture, with clover next. With both, however, avoid too close grazing. Rape and artichokes are best pastured in conjunction with clover or grass.

Green Fields

For dry-lot or pen-feeding fresh-cut alfalfa or clover are best. Rape is largely employed but is much lower in value than the first two mentioned and must be used before it becomes coarse and fibrous.

Economical Production and Health

General Rules for Feeding.—(1) Never feed more than the pigs will clean up. (2) Make all changes in rations slowly. (3) Realize that the breeding pig is an out-of-door animal. (4) Approximate outdoor conditions in the farrowing and feeding pen, i.e., supply fresh air, light, drainage, and above all avoid draughts and dampness. (5) Make exercise a prime factor with every class and age or breeding pig. (6) For economy and health see that green feed, pasture, roots, and well-cured roughage are part of the ration. (7) Remember that the pig is a poor patient and particularly difficult to treat. Strive to eliminate the cause of disease—prevent rather than cure it.

Minimizing Labour by the use of the Self-Feeder

To obtain maximum results and at the same time reduce labour to the minimum is the constant aim of the manufacturer. It has been proven that the hog may feed himself practically throughout life, and give a profit at least equal to that of hand-feeding methods, labour considered. This point is worthy of every farmer's careful consideration when labour conditions in the next few years are anticipated. The self-feeder makes possible the feeding of hogs, where labour for hand feeding is not to be had, or the doubling or trebling the extent of the operation as it might otherwise be carried out, and with less labour.

Requirements of a Good Self-Feeder For Swine

Such a device to be successful must be cheap, strong, capacious, portable, easy to construct, weighter-tight, easy of regulation for different textured meals, and most important of all, so arranged that the contents will feed into the troughs without any stoppage caused by the blocking of the meal in the hopper. Further, the troughs must be constructed to ensure the minimum amount of waste such as might be caused by the animals nosing the meal over the sides or soiling it by standing in the troughs.

A Home-Made Self-Feeder

Write for full plans and specifications if interested. Briefly, a self-feeder is a large box, in length dependent on the number of pigs to be fed—2 feet 8 inches wide and 3 feet high with a double pitch-roof, one-half being hinged for filling. In the bottom of the box is a large inverted "V" or deflector running the full length which guides the meal through openings at the bottom to flat troughs 10 to 12 inches wide on either side of the box. The width of opening may be regulated by an adjustable control-board or gate. This gate must be so attached as to have a certain amount of motion or flexibility in order that the hog by nosing against it may cause sufficient motion to break or prevent the formation of the blockades or "bridges" so common in meal bins. **Here is the important point in the self-feeder.** Unless such a device feeds continuously it is worse than useless as a feeder or labour saver. Along the trough running diagonally from the edge of the latter to the side of the feeder and spaced one foot apart, are braces or divisions, to prevent the hogs soiling or wasting meal in the troughs. Write for full plans.

Advantages of the Self-Feeder Over Hand-Feeding Methods.

1. Saves over 50 per cent of the labour. 2. Reduces waste of feed to the minimum. 3. Prevents digestive troubles due to overfeeding the pigs having full access to the meal at all times and therefore eating in small quantities frequently, instead of suddenly overloading the stomach two or three times in the day. 4. Gives the small or timid pig as good an opportunity as the more aggressive individuals. 5. Will produce gains equal to hand-feeding methods at equal or less cost.

Correct Condition for Using the Self-Feeder

Place the feeder on a platform or floor that will remain clean during wet weather and prove accessible to the pigs at all times. Provide shade of some sort, either trees or a rough shed. While this system of feeding will prove relatively economical in dry lot feeding where green food, skim-milk or water are supplied daily, **the maximum efficienyc will be reached where the feeders are placed in a good clover or alfalfa pasture.** In any case, dry lot or pasture, with or without milk products, fresh water should always be supplied, preferably running, or from some self-watering device, regularly and frequently filled.

When to use and When to Avoid the Self-Feeder

Young pigs from ten weeks of age onward may be safely and economically fed by this method. Until this age is reached it is generally wise to feed by hand, although experiments have proved that even sucking pigs may be benefited by the feeder. Shoats of all

ages, and in fact all classes of pigs to be finished quickly for market may be most profitably "self-fed.'- Young breeding stock, similarly, is benefited provided the ration is one of bone and muscle-forming nature. In general, avoid self-feeding with aged sows, particularly as farrowing time approaches.

Meals and Mixtures Adapted to use in the Sel-fFeeder

From a mechanical standpoint practically any mixture of whole or ground grains or other mill-feeds may be successfully fed. Corn, for example, is frequently fed along with clover or alfalfa pasture, for short finishing periods. For young pigs or shoats any of the following rations will be found suitable provided all hulls are fairly finely ground.

1. Shorts, fine ground oats, fine ground barley or corn, equal parts.

2. Shorts 4 parts, any of the above grains 4 parts, ground peas 2 parts.

3. Shorts or wheat 2 parts, barley 2 parts, peas 1 part.

With any of the above rations fed to young pig s skim-milk may be most profitably fed. Where such cannot be obtained the addition of tankage, meat or blood meal is recommended, say at the rate of one pound tankage to six pounds of any of the above mixtures. Where whole corn is used, one pound of tankage could be added to every eight of corn.

SOLVING THE FEED PROBLEM

A few weeks ago we heard a prominent farmer, who resides near Sussex, remark: "The high cost of dairy feeds did not trouble me very much last winter, as I grew a large quantity of peas, which I ground for my cows. I was not obliged to buy very much heavy feed." The farmer in question has a nice herd of cows and is prospering. He has made provision for a large crop of oats and peas this year.

A farmer living in one of the most prosperous sections of Sunbury county made a similar remark about the feed question. He said he had not bought a pound of feed for his cows all winter. He has a good crop of clover every year and grows also large quantities of swedes. He remarked that his cream cheque for March, 1917, was the largest he had ever received, and he gave the entire credit to the home grown feeds.

Alfalfa has been successfully grown in many parts of The Maritime Provinces in a small way. If alfalfa can be grown on a small plot where the proper conditions prevail, is there any reason why it would not grow in larger plots if the same conditions were given.

Mr. C. W. MacDougall, Dairy Superintendent for New Brunswick, has agitated for the giving of a fair trial to this useful crop. He has produced seed at Sussex that was pronounced by experts to be the finest sample of alfalfa seed they had ever seen. We believe that when our farmers will give alfalfa a fair trial by sowing it on well cultivated, drained, limed and inoculated soil, success will be assured, particularly if acclimitazed seed is used. Mr. McDougall has a small plot of alfalfa this year, where he sowed five varieties for comparison purposes last year. The various varieties are doing well and we believe the seed produced will be carefully harvested and used to sow a plot next year.

Very few, if any men in New Brunswick, have made as close a study of the feed question as has Mr. McDougall. Farmers who have given alfalfa a trial, without giving it the proper conditions for growth, would be well advised to try again in a small way and pay attention to every detail. Read the following extract from the report of the Nebraska Experiment Station. It should stimulate our farmers to try again.

A Substitute For Bran Grown on Farm at $12 Per Ton

Here is the result in brief of a test at the University of Nebraska North Platte substation to determine the effect of substituting chopped alfalfa for bran in the standard ration of 4 parts ground corn, 2 parts bran and 1 part oilmeal for dairy cows. In November, 1916, six pairs of dairy cows were selected with reference to lactation period, milk and butterfat production, age, breeding and other factors influencing their probable production during the next thirty or sixty days. One cow from each pair was put into Group A, and the other into Group B. The milk and butterfat production of the two groups had been about equal during the past month, and so far as could be foretold would be about equal during the next two months. All cows were handled in the same manner, excepting that during the first fifteen days the cows in Lot A were fed the standard ration of corn, bran and oilmeal, while the cows in Lot B were fed the same amount of grain, but in the mixture bran was replaced by chopped alfalfa. At the end of fifteen days the cows in Lot A were fed the alfalfa mixture and the cows in Lot B the bran mixture for fifteen days. Then the cows in Lot A were given the bran mixture and the cows in Lot B the alfalfa mixture for fifteen days. For another fifteen days the cows in Lot A were given the alfalfa mixture and those in Lot B the bran mixture. During two of the four fifteen-day periods each lot of cows was fed a grain mixture of 4 parts of corn, 2 parts of bran and 1 part of oilmeal, and during the other two periods each lot was fed a grain mixture of 4 parts of corn, 2 parts of chopped alfalfa, and 1 part of oilmeal. At all times there were six cows on one ration and six on the other.

The amount of grain fed to a cow was based on her milk production, but the two cows in each pair were fed the same amount of grain. The cows were fed 30 pounds of silage each, daily, and all the alfalfa hay they cared for, which is estimated at 20 pounds per head daily. During the third period one cow in Lot A, being fed the bran mixture, went off feed for a few days, and during the fourth period another cow in Lot A, being fed the alfalfa mixture, dropped in production for a few days. As one cow was off when on bran and the other when on alfalfa, these deficiencies do not influence the final results.

The six cows in Lot A while on the bran mixture during two fifteen-day periods gave 3,972 pounds of milk containing 143.3 pounds of butterfat and lost 32 pounds in weight. The same six cows while on the alfalfa mixture during two fifteen-day periods gave 4,052 pounds of milk containing 138.7 pounds of butterfat, and gained 223 pounds in weight. The six cows of Lot B while on the bran mixture during two fifteen-day periods gave 4,244 pounds of milk containing 158.4 pounds of butterfat and gained 254 pounds in weight. This same group of cows while on the alfalfa mixture during two fifteen-day periods gave 4,332 pounds of milk containing 163.6 pounds of butterfat, and gained 1 pound in weight. Bringing together the results from both groups we find that the twelve cows while eating the bran mixture durin gtwo fifteen-day periods produced 8,216.5 pounds of milk containing 302.7 pounds of butterfat, and gained 222 pounds in weight. The same twelve cows while on the alfalfa mixture during similar periods produced 8,384.5 pounds of milk containing 302.3 pounds of butterfat, and gained 224 pounds in weight.

During the test with twelve cows for a period of two months chopped alfalfa was substituted for bran in the standard dairy ration of 4 parts of ground corn, 2 parts of bran and 1 part of oilmeal, with no appreciable effects, either favorable or unfavorable. If these results are the same as will be found in general practice, then alfalfa fed in this manner has the same feeding value as bran. Since the same amount of butterfat and practically the same mount of milk was produced from the ration containing chopped alfalfa as from the ration containing bran, the difference in the cost of production is only the difference in the cost of the alfalfa and the bran. Valuing a good quality of choppel alfalfa at $12 per ton and bran at $30, the saving in cost of feed, due to substituting chopped alfalfa for bran, amounted to 13.6 cents per 100 pounds of milk, or 11 per cent. of the cost of the feed eaten by the cows in producing this milk.

University of Nebraska Substation.

GOOD WATER SYSTEM AN ESSENTIAL PART FARM EQUIPMENT

One of the most important features of a well equipped farm is its water system, and notwithstanding this there are comparatively few places where anything approaching a complete outfit has been established.

The first factor in this equipment is the supply. Where a perennial spring or never failing well of good, pure, sparkling water is at hand, properly located, this phase of the problem is solved. In the absence of either or these, however, and where the farmer has to make a move in that respect, it would be advisable for him to be practically certain that the results will be sure and satisfactory regardless of a considerable difference of expense between either of the above and a temporary or uncertain supply.

The location of a well is worthy of special consideration. In the case af a farm that does not exceed half a mile or in some central position may be in length, one well located at the house or in some central position may be made to answer the purposes of the whole farm. By having some kind of power for pumping, the water may be forced through a small tank in the house into a larger one, outside, at or near the well, and from there conveyed to the barns and other out-buildings or to a trough in the yard or lane for convenience in the summer when the cattle are at pasture. Where the farm is more than half a mile in length it is usually better to have another well to water the stock pasturing in the rear of the farm, both to eliminate the inconvenience of bringing the cattle up to water in the middle of the day in hot weather and to encourage the cows to drink large quantities by having the supply convenient to them, without their having to make a long journey to the barn which might often do them as much harm as the water would do them good. A heavy milking cow is working hard enough securing her feed and manufacturing it into milk without taking long walks to secure water. It is better policy to take it to her.

The kind of well advisable will depend largely upon local conditions. Where there is a gravelly formation not too far below the surface a "drive well" will furnish an abundance of good water and in some sections a dug well is useful, but in most districts nothing is as sure as a good drilled rock well. Of course the initial cost will be considerably greater, but when a supply is once assured, it can usually be depended upon for all time. One big advantage to be found in the drilled well over the old fashioned dug well is the fact that it is not dangerous and not easily contaminated with outside impurities.

Having secured the well and located it at or near the home, so that the water may be forced through it on its way to the storage tank, let us look at further details of some definite system. It is not absolutely necessary to have the well or storage tank at or near the house, but it is preferable there for several reasons. In the first place that is the most convenient place to look after the pump and whatever power is used to operate it. Even when the best of care is taken of machines they sometimes go wronk. If placed quite near the house, where it can readily be seen, the windmill, gasoline engine or whatever other power is involved, may be observed now and then better than at any other place. On most farms the men are away from the buildings during a greater part of the day and if pump and power is at the barn or far from and out of sight of the house, there will be no one around to observe anything going wrong unless the burden is imposed on the women. Secondly, every farm house should have its supply of water furnished by the farm power. This is easier accomplished when the well and power is near the residence. Thirdly, if fresh water is wanted in hot weather and there is no wind to operate the mill or the other power is not working, it is only a step to the well. Fourth, the nearer the well to the house the less will be the power required to force the water through it to the storage tank. Fifth, if the power is at the house and the tank at the barn, much more power will be required. Sixth, if both the well and power are at the barn it will be difficult to get fresh water at the house. Of course both may be located at any reasonable distance away from either house or barn and the same results secured at the greater expense of power, heavy work for pump, making repairs more frequently necessary and increasing care and attention.

Some will think that the storage tank should be located at the barn on account of greater ease in protecting it from freezing. To this objection it may be said that a tank of water will freeze in the barn unless protected, and it is usully more or less of a nuisance, sooner or later leaking and causing trouble. A tank out of doors can be protected against freezing without great expense by enclosing it in a small, warmly built structure suitable to its si e. It may even freeze a good deal without doing any damage. Then, too, the daily pumping of warm water from the well into it will have a great influence in preventing severe freezing. Again on many farms the elevation of the house is great enough above the barn so that the reservoir may be built low down and covered in the winter to prevent damage by frost.

No doubt the ideal water system for the farm is provided in the pressure tank, which to all practical purposes is worked on the same principal as an ordinry steam boiled. The water is forced into it by a pump until the desired pressure is obtained when it may be carried to any building about the farm high or low without any further storage or any more expense other than the piping and watering troughs or basins. In addition to its value at the farm barns, outbuildings, etc., it may be used as a means of fire protection as water may be carried over the highest buildings on the farm. Again it may be used as a complete house system, providing water for lavatory, bath, laundry, or any other purposes for which it is needed. This system will cost more but where a farmer can afford it, he had better investigate it before proceeding with any other. There are companies advertising in farm papers who will be pleased to furnish estimates and tender on the installation of such a plan. If, however, any farmer interested in this matter has not the necessary cash on hand, or is not reasonably sure of having it in time to meet his payments, he had better be content with some simple plan that will answer every purpose,

INSURANCE AN INDIVIDUAL NECESSITY

At thirty-five, a man has a life expectancy of about twenty-five years; that is to say, the average man of thirty-five will live to the age of sixty. But every one of a group of one thousand men, all of the age of thirty-five, will not reach three score. Ten of them will die between the ages of thirty-five and thirty-six. There will be a steadily mounting annual death loss, which long before the expected age of sixty is reached, will have decimated seriously the ranks of the original thousand.

It is this uncertainty of life that creates the need of insurance. If a man were able to say that he would live and exercise his earning power until he was sixty years of age, no particular need would exist for life insurance. He could carry his own risk, so to speak. But not being thus circumstanced, he requires to protect his family and estate against loss in case of death; his family against the loss of his earning power, and his estate against loss resulting from the removal by death of the head of the organization in the midst of life's activities. A straight life insurance policy, paid up by the time the insured reaches the age of fifty-five or sixty gives the best means of protection in those circumstances. A man requires also to protect himself against want in old age. An endowment policy paying a lump sum at a certain age or an annual payment during the lifetime of the insured, is the best means of ensuring independence during the closing years.

Several hundred varieties of insurance policy exist, but these two possess every essential for the protection of the average person and his dependents. The important point about life insurance is to have it, not to be merely thinking about buying a policy at some future time; to secure it at an age, when it may be purchased to the insured's advantage, not later in life when rates are higher and his chance of living smaller.

ECONOMIZE LABOR BY A SYSTEMATIC PLANNING OF WORK

It requires a good deal of ingenuity nowadays to farm successfully with the amount of help that is available. Most of us are engaged in producing milk, beef or pork. To be profitable, the feed must be largely home-grown. To accomplish this properly is a pretty fair contract under existing conditions, yet I have noticed time and again that some farmers attempt to raise almost every crop that will grow in their latitude.

In economics there is a principle known as the "division of labor", which may for the present purpose be best defined by means of an illustration. For instance, because a farmer in Carleton county grows potatoes on a large scale and makes money, it does not naturally follow that a busy dairyman in King's County can add potato growing to his operations and be successful. The man who makes potatoes his specialty must employ modern machinery to reduce the cost of production to its lowest possible point. He is therefore able to sell his output to the dairyman at a figure even lower than it would cost the latter to grow his own supply. The suggestion is plain. If farmers would give their undivided attention only to such crops as are necessary to their special line, and which they are equipped to produce cheaply, buying other supplies from other specialists, both parties to the transaction would benefit, and the cry for help would, in a large measure, cease.

It frequently happens that a good deal of labor is wasted in trying to crop land that is not in condition for cultivation. Suppose it needs underdrainage. Several things are likely to happen that will make cultivation unprofitable. Delay in spring means that in order to get the work done on time, probably double the help will be required. Then, too, undrained land requires two or three times the amount of labor in preparing a seed bed. It is not an uncommon sight to see men shoveling furrows across a field to let off the surface water. Ten chances to one the crop on this field will not pay expenses. Figure up the cost of opening these furrows, add the extra labor in tillage involved, plus the difference between a poor crop and a good one and the result ought to balance the outlay for tiles to put the land in first-clsas condition.

Sometimes, owing to size or peculiarity in shape of a farm, there are fields so far removed from the barn that much time is lost during seeding and harvest in going back and forth. Would it not be better to utilize this land for pasture, giving an occasional dressing of phosphorus. Then, instead of having the remainder of the farm laid out in many small fields, have but one to each year of the rotation. That is, if a three year rotation is followed, only three fields will be required. This means an absence of weedy fence rows that require attention at a most inconvenient time, larger machinery may be used and there is less turning with teams and implements.

In most cases it will be found that the man whose work is systematically directed will accomplish more than the man who has plenty of help but no system.

BUTTER FAT AS A FOOD

The following statements of J. H. Rushton of Omaha, Nebraska, about the nature and function of butter fat as a food are interesting. He writes:

"Milk is the universal animal food, provided by nature for the support of the young of its kind.

Growth is one of the principal functions of the young in animal life, and this growth is caused by a multiplication of cells in the animal tissue, meaning by 'animal tissue' everything connected with the animal from a 'life' point of view.

"The ordinary food taken in by animals supports life in the form of maintaining life—maintaining the body; but maintenance of life and maintenance of the animal body, is very different from growth, which means addition to the body and to life. Maintenance of cell life is one thing; but an increase of cell life is another thing.

"Therefore, the facts are that nature has provided a universal food for the young of animals, and the great function of youth is growth, and that this universal food possesses the elements of growth in it. These are basic facts—broad and general in their application, and well known in our own experience.

"It is becoming recognized that skim milk forms a diet very favorable for growth. It is admitted and recognized that butter fat contains in it this element to promoe growth and butter fat is the basis of butter.

"Therefore, butter is an article of food, not only capable of maintaining animal life, but of promoting the growth of animal life.

"It follows from this, and our experience supports the argument, that the more universal the use of milk and the constituent elements of milk by the people, the more the function of animal life is sub-served; and the more growth there is. Other foods have large maintaining power, but very few, if any of them have this growth power.

"The necessity of milk and milk products as a human food, as being conducive to health and as tending to longevity of life, is recognized by the medical fraternities and by all health bodies, and is well founded in the experience of mankind from the time of Adam until the present. The more liberal and the more general its use, the better the youth of our land will be in stature and in health.

"When you buy oleo, you purchase animal and vegetable fats in various proportions, that have more or less power to maintain life, but when you buy butter you have this same power plus the power to promote growth in the human race.

"You get something when you buy butter that you do not get when you buy oleomargarine, and it is this quality of promoting growth that has given to butter its universal use among enlightened and intelligent people, and give nto milk the place it now occupies. All the efforts that can possibly be made to improve the palatability of milk and improve the palatability of butter go to increase the use, and thus increase this power to promote growth in the human race."

WEEDS

With the call for more production there may be a tendency to increase the acreage of high producing crops such as the root and hoe crops on the farm. In preparing for these crops this year it will be well to thoroughly bear in mind that no amount of cultivation after the crop is in can make up for a lack of cultivation before the crop is planted. If the ground is properly prepared for the seeding and planting, the battle is largely won. By thorough tillage of the soil before planting thousands of tiny weeds will be killed which would otherwise cause trouble in the growing crop. By preventing the weeds from growing the crops are given a better opportunity to develop and produce the food which is required by Canadians in Canada and the Allies in Europe.

HORTICULTURE

RATE OF PRECOOLING FRUIT

In establishing precooling plants, there has been need of more information concerning the rate of cooling in the centres of the different packages of various kinds of fruit when exposed to a cooling air of a given temperature. The tests discussed herein were made with this end in view.

There has also been need of reliable information regarding behaviour of summer fruits when precooled quickly in four or five hours' time, using a temperature below freezing to do the work, as compared with the behaviour of fruit cooled slowly over a period of eighteen or twenty-four hours.

In making these tests the given variety and type of package of fruit has commonly been divided into four lots, one-half of which were stored at 40° F., or a refrigerator car temperature, and half at 32° F. One lot in each temperature was cooled rapidly at a temperature lower than 25° F., while the other lot was cooled gradually, using a temperature of 40°, for several hours. In rapid precooling the fruit was removed from the low temperatures as soon as the interior of the package was cooled to a temperature between 32° and 40° F., so that no freezing took place.

In securing the records of the rate of cooling, extension mercurial recording thermometers were used, having the sensitive bulb in the centre of the packages tested.

In studying these records and applying them to commercial conditions, it is well to consider the fact that they were made with the temperature of the air surrounding the package constant or very nearly constant during the entire period of cooling. Under commercial conditions, unless a large reserve of refrigeration is on hand, and is controlled automatically, the temperature of the cooling air is bound to be higher when the fruit is warm at the start of cooling than it will be after cooling has progressed.

Resutls

In stating results averages will be given showing wastage after a long storage period, so as to make comparisons

Low temperatures are not satisfactory with tomatoes. Tests thus far with tomatoes have not been conclusive in arriving at the best temperatures for precooling or storage. Temperatures slightly below 32° F. may be safely usee if precooling is stopped as soon as the tomatoes reach a temperature of 38° F.

Conclusions

Tender fruits such as raspberries, cherries, plums and peaches may be precooled in a short time without injury to the fruit using temperatures as low as 15° F., providing the fruit is removed from the low temperature before its temperature reaches the freezing point.

With strawberries, tomatoes, cucumbers and cantaloupes extremely low temperatures should be used with caution, although it is safe to use temperatures lower than 32° F., providing cooling is stopped when the temperature of the fruit reaches 38° F.

With the exception of the fruits mentioned, there is no danger of injury from low temperatures unless freezing actually takes place. Freezing will not take place for some time after the temperature of the fruit reaches 32° F. Even when using a cooling temperature of 15° F., the temperature of the fruit will not reach this point for several hours.

By using an air temperature of 15° most basket fruits will cool from 75° F. to 40° F. in four hours.

By using an air temperature of 32° F. most basket fruits will cool from 75° F. to 40° F. in ten hours.

By using an air temperature of 38° most basket fruits will cool from 75° F. to 40° F. in eighteen hours.

For the purpose of efficiency, precooling plants should be designed to do their work rapidly. The warehouse type of plant should be designed to precool fruit from 85° F. to 40° F. in not more than ten hours' time. Fruit being received in the afternoon may thus be shipped the following forenoon, clearing out the rooms for the afternoon's receipt of warm fruit and increasing labour efficiency by using men in the afternoon for receiving.

Rapid cooling shortens the time of despatch of the shipment, not only the extra time needed for slow cooling, but often as much as twenty-four hours where long-distance freight trains are made up but once daily.

Strawberries.

Low Temperatures used, 20° F.

	Average Percentage of Waste. Cooled Rapidly.	Cooled Slowly.
Held 6 days at 32° F.	9.0	0.0
Held 6 days at 40° F.	9.0	12.7

No injury was apparent from the rapid cooling and although the averages show the rapidly cooled to be superior, no practical difference could be seen in making inspections.

Cherries—Sweet.

Low Temperatures used, 12° F. and 15° F.

	Average Percentage of Waste. Cooled Rapidly.	Cooled Slowly.
Held 14 days at 32° F.	0.0	0.0
Held 14 days at 40° F.	6.93	6.55

With the Napoleon Biggareau variety a slight injury was apparent from using 12° F., so slight to be negligible. Otherwise, no difference could be seen between the two methods.

Cherries—Sour.

Low Temperatures used, 17° F. and 20° F.

	Average Percentage of Waste. Cooled Rapidly.	Cooled Slowly.
Held 10 days at 32° F.	6.67	5.41
Held 10 days at 40° F.	10.01	12.73

No injury was to be seen from rapid cooling.

Raspberries.

Low Temperatures used, 20° F.

	Average Percentage of Waste. Cooled Rapidly.	Cooled Slowly.
Held 6 days at 32° F.	0.0	0.0
Held 6 days at 40° F.	2.68	1.90

Averages of wastage favour slow cooling. The amount of difference, if any, could be seen in the general appearance of the fruit.

Plums

Low Temperatures used, 15° F. and 20° F.

	Average Percentage of Waste. Cooled Rapidly.	Cooled Slowly.
Held 20 days at 32° F.	2.55	1.96
Held 20 days at 40° F.	6.97	7.36

No injury was apparent from rapid cooling.

Peaches.

Low Temperatures used, 15° F. and 20° F.

	Average Percentage of Waste. Cooled Rapidly.	Cooled Slowly.
Held 20 days at 32° F.	0.0	0.84
Held 20 days at 40° F.	0.32	1.07

No injury was apparent from rapid cooling.

Tomatoes.

Low Temperatures used, 15° F.

	Average Percentage of Waste. Cooled Rapidly.	Cooled Slowly.
Held 20 days at 32° F.	0.0	16.88
Held 20 days at 40° F.	18.57	14.26

DUNLOP TIRES

A Great Response!

Watch "Dunlop Tires" in the emergency. There's a wealth of security in that response to the brake.

A. 73

"SPECIAL" - "TRACTION"

TO RESTORE VIGOR AND STRENGTH TO A FEEBLE PLANT

The amateur gardener who has a plant that has become feeble because of improper treatment, and that he desires to save, quite often in his zeal does just the wrong things. He takes the plant from the pot, either removing all the old soil from the roots or leaving on the roots the mass of soil entire; he secures another pot, very much larger, and uses for repotting soil with which he has that very hour very improperly mixed a large proportion of animal manure, not well rotted but fresh from the stable or henhouse, or of some strong chemical fertilizer. Having repotted the plant in this crude, overrich, untempered mixture, not firmly, but loosely, he places it somewhere with little regard to the temperature or humidity or sun or shade. He waters it heavily every day, so that the soil soon becomes soggy and sour, as there is directly after transplanting little root action in the plant to enable it to use this water and carry it off through its foliage. And then his plant dies.

It is foolish to try to revive a nearly dead or very feeble plant unless the specimen is very rare or is valued for some personal and sentimental reasons.

The Right Kind of Soil

Given such reasons, however, consider what means should be employed to make the plant again strong and vigorous. First examine it for sucking insects, such as plant lice, green flies or scale bugs, and if these are found spray the plant with some good contact poison such as kerosene-soap emulsion.

If chewing insects are found, such as worms or beetles, use a stomach poison such as arsenate of lead with Bordeaux mixture; the arsenate will kill the worms or beetles, and the Bordeaux will be a remedy for any fungous disease that arises from insect injuries.

A hand sprayer, which will throw a mist-like spray, should be used to apply these insecticides. On a feeble plant it is highly important that the minimum strength of solution be used; the maximum strength is much too lokely to burn the foliage.

The spray should be applied twice a week till all insects are destroyed. If the plant is quite small the insecticide may be applied directly to the insects with a small, soft, round paint brush, especially if the insects are not very numerous. Meantime keep the soil in the plant pot moderately wet, and the plant in the proper temperature and light.

THROUGH CAR SERVICE MONCTON TO LEVIS, VIA EDMUNDSTON—GOOD CONNECTION FOR FREDERICTON.

Summer Time Table Canadian Government Railways

With the summer time table in effect Sunday, June 10th, passengers will be able to leave Moncton 4.00 p.m., Tuesday, Thursday and Saturday and travel in through car, via Edmundston to Levis, arriving there at 10.25 a. m. the following day. Returning the through ar will leave Levis Monday, Wednesday and Friday, 4.30 p.m., and arrive at Moncton at 12.05 noon, Tuesday, Thursday and Saturday.

By the same trains and on the same days from Moncton there is a good connection at McGivney for Fredericton, passengers arriving in the Capital City at 9.45 p.m. Returning passengers can leave Fredericton at 6.40 a.m., and arrive in Moncton at 12.05, noon, Tuesday, Thursday and Saturday—the quickest time between the two cities, Moncton and Fredericton.

the brood builds up the colony for next year, unless there is to be another important honey-floiw. This brood is very valuable for forming nuclei, because these, started early with a laying queen, or ripe queen-cell, will build up into strong colonies before winter. Increasing in this way with brood from strong colonies during the honey flow is the basic principle upon which an apiary can be quickly built up, while at the same time an almost full honey-crop is secured.

In newly-formed nuclei containing brood in all stages, there is always more or less desertion of bees and consequent death of the young brood and sometimes chilling and death of the older brood, even when the nuclei are skilfully made by an experienced apiarist. Further, queens may not be immediately obtainable, or they may be lost in introduction. Robbing of the newly-formed nuclei has also to be guarded against, but during the height of the honey-flow only carelessness will cause this; towards its end, however, the danger of robbing grows so great that it is difficult to maintain newly-formed nuclei even when strong. Desertion may be checked by stopping the entrance with grass; the bees will make their way out when the grass dries and shrinks in about two days, but care must be taken to avoid overcrowding the confined bees, which would lead to stifling, especially in hot weather. A good way to overcome the loss of young brood is to place the brood over a queen excluder a week before its removal from the parent hive. This may be done in the ordinary course of relieving congosiion in the brood chamber as a means to discourage swarming, a frame or two of empty comb or of foundation being placed in the brood chamber when the brood is raised.

All of these risks may be greatly minimized by proceeding as follows:—Have all the queens' wings clipped (Tthis is not essential), and when a colony of a strain that it is desired to propagate swarms, move the parent hive to a new stand, and let the swarm return to an empty hive placed on the old stand, the queen having been picked off the ground and placed in the empty hive. The field bees will now join the swarm, and the super should be transferred from the parent hive to the swarm which will produce the crop of honey. The colony, now depleted in bees but rich in brood, is divided a week later into three to six nuclei, each nucleus consisting of two or three combs containing brood and honey carrying two or three queen-cells containing queens soon to emerge, with the adhering bees.

This method has the great advantage that it not only controls and satisfies the troublesome swarming instinct but it helps to secure the desired ends by natural means. The honey gatherers are segregated into a strong force, and the brood, being mostly capped, is not likely to get chilled; the bees desert neither it nor the queen-cells readily, and all trouble in raising and introducing queens is avoided. The bees in the newly-formed nuclei are in the post-swarming stage, when their instinct is to spread themselves over and incubate as much brood as possible, and especially the queen-cells.

The beginner should be warned not to divide the parent colony into two many weak nuclei, but this fault may be rectified in the autumn by uniting. The ideal conditions for building up nuclei are a slow honey-flow throughout August and early September. Fortunately these are supplied in most Canadian localities by goldenrods and asters or by buckwheat.

Mismated queens may be replaced any time up to the first or second week in October, preferably not during the robbing season.

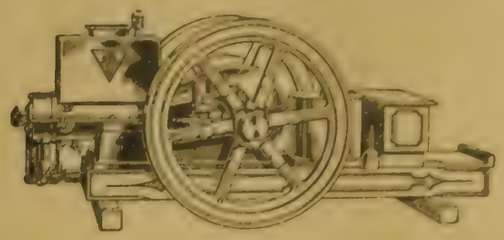
SPRAYING

In our issue of February 6th, we published a paper on "Some Results from Spraying Work of 1916 and Sprays Recommended for 1917", read by Geo. E. Sanders before the recent Nova Scotia Fruit Growers' Association at Bridgetown. We have heard some very favorable comments on Mr. Sanders' paper.

One good authority on conditions in the Fruit sections of Nova Scotia told us recently that the paper in question was right up to date to the farmers of the valley, but is one or two years ahead of most of the Exp. Station men. The farmers all are sure that they have burned apples off the trees and they are sure that Bordeaux is safer for the last summer spray. They know that if you do not use Bordeaux for the "after the blossom" spray you will get very little russetting from its use at other times. They know that for two years they have used and seen arsnate of lime used with lime and sulphur and that it was safer and much better to use than arsenate of lead with the same material. All this seems to be news to most of the experiment station men, but it is something that dozens of people in the valley have been watching for two years and are now sure of.

Another party told us it is great fun to see the way the dicerent experiment station men treat the new spray calendar, most of them are as yet very sceptical. I have been on a two weeks trip over the valley and I have only had all that Messrs. Sanders and Brittain have published and more that they have not yet published corroborated and no one raising the slightest criticism of the spray calendar, for it jibes I find, with the experience of dozens of men throughout the valley who have tried it out but never brought their tests before the public before.

HARD JOBS MADE EASY
if you have an



Alpha Gas Engine

THE farmer who goes on doing all his work by hand is wasting a lot of time and energy.

He could accomplish a great deal more work, and do it more quickly and more cheaply, if he had a good gas engine.

For some reason, many farmers, who without hesitation will buy a mowing machine that they can used only seven or eight times a year, will balk at buying a gas engine with which they could save time, money and labor every day. They seem to regard it as a luxury, when as a matter of fact it can be put to so many different uses that it will save its own cost more quickly than any other machine on the farm.

Go in and see the local Alpha agent. Let him show you for how many different purposes you can use the Alpha, and why it is the most economical engine to buy and the most satisfactory to own. If you don't know who handles the Alpha in your neighborhood, write us for his name.

The sooner you get an Alpha, the sooner it will pay for itself

Ask for catalogue, prices and complete information. Made in eleven sizes, 2 to 28 H. P. Each furnished in stationary, semi-portable or portable style, and with hopper or tank cooled cylinder.

DAIRYING.

CHEESE FROM SKIM MILK

Subscriber asks for a method of making cheese from skim milk.

In making skim-milk cheese granite pails should be used, as allowing sour milk to stand for any length of time in a tin pail will give it a metallic flavor.

Method No. 1

Heat the milk to eighty or ninety degrees F., and let it stand at this temperature until it becomes thick and sour. Then place the pail containing the milk in boiling water; break up the curds and raise the temperature to from 105 to 110 degrees F., stirring it gently so as not to break the curds up too finely. Cook at the above temperature for from twenty to thirty minutes.

When the curd begins to get firmer, pour it into a clean sugar sack or o cheese cloth bag and hang up to allow the whey to drain off, then wash the curd by pouring a small quantity of water into the sack at from 85 to 90 degrees F. This will removo the rancid flavor.

When the curds are fairly well drained, add salt at the rate of one-half teaspoonful per pound of cheese, then keep it in a cool place until ready to serve. When serving, add a little sweet cream and work it well into the curds with a long spoon. This will give the cheese a fine texture. Never add cream until ready to serve, as the acid in the cheese will cause the curd to become sour, especially in hot weather.

Method No. 2

Heat the skim milk up to 75 or 80 degrees F. and, in order to hasten the process of making, fifteen to twenty per cent of starter can be added, which will cause the milk to curdle in a much shorter time. When a firm curd has been formed it is broken up by cutting with cheese knives or a wire spoon.

After the curd is broken up, it should be heated to from 98 to 100 degrees F. by applying heat gradually and stirring continually. It should take about twenty-five or thirty minutes to bring it to this temperature. Maintain it at that temperature for about twenty or twenty-five minutes or until the curd feels fairly firm and the whey appears clear. Too low a temperature in cooking the curds produces a soft, pasty cheese, which will develop a high acid flavor, while a high temperature will produce a dry, granular and corky cheese.

Drain the curds by putting them in a cheese cloth bag in small quantities and hang it up to drain. When the whey has practically ceased to run, it is ready to add the salt. When the curd is taken from the strainer, it should be in a single mass. It should be thoroughly broken up and salt added at the rate of one ounce to five pounds of curd. If a rich cheese is desired, cream or butter may bo added.

SELLING MILK OR CREAM

Subscriber, writes: "I have a number of cows freshening this summer. I am not certain whether it will pay me best to sell my whole milk or simply the cream. What would you advise?"

This is a difficult problem to solve from the meagre information furnished. It will depend largely upon conditions which are not outlined. For instance, if a number of hogs and young calves were being kept, it would be necessary to keep the skim milk at home and market the cream. The distance from town will also be a determining factor in the marketing of the dairy output. If located at a considerable distance from town the hauling of cans of whole milk is not to be recommended in comparison with marketing the cream alone. The relative prices of milk and cream will be a further regulating influence. While these figures are not given by our subscriber, there is a basis upon which we can figure this problem and allow the shipper to judge for himself under conditions prevailing in his locality.

Take a dairy of twenty cows, with an average butterfat test of four per cent. Will five cents per quart for milk be as profitable to the owner as cream sold at forty cents? Forty quarts of milk at five cents bring $2. The forty quarts of milk weigh eighty-six pounds. If four per cent is fat the fat weighs 3.44 pounds. One quart of thirty per cent cream weighs approximately two pounds; its fats six-tenths of a pound. Dividing six-tenths of a pound into 3.44 pounds we learn that the eighty-six pounds of four per cent milk contain 5.73 quarts of thirty per cent cream, worth at forty cents per quart, $2.29. Here is a gain of twenty-nine cents per can above the sale of milk at five cents. Nor is this all, for seventy-four pounds of skim-milk remain at home. Authorities claim that this is worth one-half as much per hundred pounds as oats is worth per bushel. Alberta oats are worth about 62 cents, thus making the value of this skim-milk 31 cents. This added to the 29 cents above, shows a total over the selling of milk of 60 cents per forty quart can. When a dairyman is dependent upon the sale of fats, he will retain the rich producers in his herd. The tendency is for the test to creep up. When it has reached 4.25 or 4.5 per cent the gains are greatly increased.

Still there are features to consider in the cream business. The owner must concentrate his business. His dairy room must be equipped so he can separate, test and hold his cream until shipped. By carelessness he may lose fats in his skim-milk or in shipping, so that frequent tests will be necessary of both the cream and the skim-milk as well as of each cow. If the cream is sold to dealers who pasteurize, icing, pasteurization and cases to hold the cans when iced will not be required, but usually a better price will be received if the cream is pasteurized and sold to consumers or those who retail direct to consumers.

Every Farm Should have an "Ayrshire"
She is a heavy milk producer, rich in butter fat—very prolific.

SANITARY CONDITIONS REWARDED BY MORE MONEY

The Dominion Dairy and Produce Company, which is operated by the Dairy Branch of the Department of Agriculture for Saskatchewan, and which supplies a large percentage of the milk used by the residents of Regina, has recently outlined an attractive and up-to-date method of paying for its milk supply. Mr. W. A. Wilson, dairy commissioner, has written each milk shipper that if at the end of the year he can show a clean bill of health for his cows, or in other words, can furnish a certificate from a qualified veterinarian showing that his cows are free from tuberculosis, he will be paid three cents per pound for each pound of butter fat his milk has contained, in addition to the regular payments he has received during the year.

In addition to being paid extra for healthy cows he will receive two cents extra for each pound of butter fat, if his stable, milk house and general surroundings are sufficiently sanitary to score 75 points or over in a possible 100, in accordance with the score card used by the health department of Regina. In connection with this inspection the dairy branch are co-operating with the city health department, and their reports on the inspection of these dairies will be used and will form a basis on which these extra payments will be made. It is doubtful if this system has ever been tried in any other part of America, but the principle of paying dairymen to take extra care and pains in connection with their herds and milk shipments is right, and should work out to the satisfaction of milk shippers and also tend to materially improve the supply of milk.

The system of paying for quality is not new with the dairy branch of Saskatchewan, as during the past few years this system has been followed in connection with cream shipments at all creameries operated by the dairy branch. Three different standards have been made for cream, and those who ship the highest grade receive five cents per pound more for each pound of butter fat than do those who ship the lowest grade. This system has so improved cream shipments that it has enabled the co-operative creameries to produce a butter of exceptionally high grade, which sells on the British Columbia and Montreal markets at a considerable premium over local butter. In connection with milk shipments it is somewhat of an experiment, and is subject to later modifications, but should work out to the advantage of both producer and buyer.

CLEAN DAIRY UTENSILS NECESSARY FOR CLEAN MILK

Most of the bacteria which get into milk come from the dirty cow and from the utensils, such as cans, pails, strainers and separators, which have not been properly cleaned. In winter the cows are likely to become dirty from confinement in the barn, but in summer they are easily kept clean so that they are then of little relative importance in contaminating milk. On the other hand, a far greater number of bacteria get into milk from dirty utensils in summer than from a dirty cow in winter.

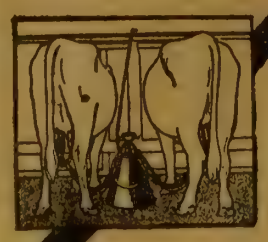
A bacterial count recently made from some of the rinsing water left in an eight gallon can, which had been washed twelve hours before, showed the can to contain more than three billion bacteria. Eight gallons of milk placed in this can would have received a contamination of nearly 100,000 bacteria for each cubic centimeter. This can had been thoorughly rinsed and left covered in a room where tho temperature was about 70 deg. F. An experiment made during the winter when the temperature was below 50 degrees showed fewer than 3,000,000 bacteria in a can similarly treated, which would mean a contamination of fewer than 100 for each cubic centimeter of milk.

A can which was rinsed subsequently heated with steam and then turned right side up with the cover off until dry, contained approximately 200,000 bacteria or a contamination of about 7 for each cubic centimeter.

Experiments of this sort which hve been carried on at the University of Missouri College of Agriculture indicate that the point of chief importance in the care of dairy utensils, especially in warm weather, is thoroughly drying after cleaning. Cleaning will remove a large per cent of the bacteria and much of the food for their growth. Application of steam for thirty seconds kills very few, but it will supply heat to dry the utensils which prevents bacterial growth so that there will be practically no more presont twelve hours later than five minutes after washing the utensils.

Much emphasis has been laid upon thorough cleaning of utensils, and rightly so, but the process of drying is equally as important in warm weather. Drying should not be done with a cloth, but by heating the utensils in hot water, steam or oven sufficiently to evaporate moisture.

General recommendations for the care of utensils are: 1. Rinse in luke-



"With your Milking Machine I can Produce Milk of Superior Quality"

The writer of the letter below is known throughout his district as a keen and rather critical judge of dairying methods and equipment. They say he is a "crank" on quality! Certainly the John D. Duncan Co., of Montreal, are most particular about the purity of the milk they get for their patrons.

RIVERFIELD, QUE., Jan. 25, 1917

Gentlemen:—
I have noticed some of the testimonials you are publishing and thought I would let you know how I like the Empire Milking Machine and Empire Engine which I purchased from you in the month of April, 1916. It has given entire satisfaction. I have had considerable experience with engines for many years, and am consequently in position to appreciate the merits of the Empire, and recommend same as one of the most reliable for milking machine and general farm work.
With your Milking Machine I can produce milk of superior quality, according to the statement of the John D. Duncan Co., to whom I have been shipping. I find that the machine is in no way injurious to the cows or teats, and no other trouble has been experienced. The speed at which the machine can milk is regulated by the class of cows and the quickness of the operater.
J. R. McKELL.

EMPIRE
Mechanical Milkers

produce milk of high quality, at the same time that they save time, reduce expense, increase profits, and make it possible to keep up and even increase the number of cows milked, in spite of the growing scarcity of help, They certainly are worth investigation.

Write for Booklets explaining the correct natura principle on which the Empire works, and giving the experience of prominent Dairymen who are using it. Address Dept. L

Wear PALMER-McLELLAN'S Chrome Tanned Farm Boot

THIS SUMMER

POST PAID TO YOU

$4.50

"The Boot with the Moccasin Comfort"

Here at last is the perfect combination of boot and moccasin. The general shape is that of a moccasin, but the boot is built on a last, with a long solid counter to hold up the heel. It has all the easy foot fitting comfort of a moccasin, and, at the same time, it will stand right up and keep its shape with any boot.

The new chromoil leather used is simply wonderful. The chromoil tanning process produces a through-and-through, instead of a surface, waterproof, and a leather much stronger and more durable than any other. These new farm boots will not crack and shrivel when dried by the fire. They remain pliable in weather that freezes other oil-tans. They outwear any other boot of their kind on the market, and give solid comfort and satisfaction every day.

If you have any trouble getting these new Palmer-McLellan Chromoil Tanned Farm boots locally, mail us the price and we will ship you a pair postpaid.

Men's Sizes 6 inches high, per pair $4.50

warm water as soon after use as possible. 2. Wash in hot water containing washing powder which will remove grease. 3. Rinse in clean hot water, drain and place right side up until steam is not available, sunning will give effective results. 4. Invert in a clean protected place when dry.

SUBSTANTIAL INCOMES

What did your best cow earn for you last year? A seven-year-old grade in a herd near Oxford Mills, Ont., that milked from March 30, 1916, to Jan. 30, 1917, gave 363.9 lb. fat, which at 45 cents per pound equals the substantial sum of $163.75. Perhaps you got more.

Fortunately, the owner of this herd is keeping records of each cow that he owns and has the satisfaction of knowing that six out of his fifteen cows earned over $150.00 each.

With milk weighed every tenth day, and a composite sample tested once a month, the actual yield of each cow for her full period of lactation can be found with but little trouble.

Milk and feed record forms are free on application to the Dairy Division, Ottawa. A study of records should mean in increase in your cows earning capacity by at least fifty per cent. in three years.—C. F. W.

TO CONTROL TUBERCULOSIS

The Dominion Government is taking rigid measures to eradicate tuberculosis among the dairy herds in Canada. With its increasing live stock population, this question is a vital one to the West, and yet one to which few private owners of herds have paid any great attention. The government has recognized that the dairy man is too little encouraged to purge his herd of all those which re-act under the tuberculin test, and, according to a dispatch from Ottawa, not only will they deal more strictly with cases detected, but they will give compensation to the owners of animals slaughtered.

Where cattle have been destroyed for tuberculosis, the Dominion Government will refund to the owner one-half of the value, and where the animal has been slaughtered at the request of the owner, the government will refund two-thirds of its value. By an Order-in-Council passed lately, the government will in future license all dairies and will refuse license to all dairies failing to conform to a certain standard. Dairies receiving milk from herds containing re-actors will be prohibited from selling that milk until it has been pasteurized.

DAIRYMAN LOSING MONEY

Tabulations from the big dairy mass meetings throughout New England May 7, are fast being made. Sec Pattee of the N E M P A says reports so far show farmers are selling cows in 24 counties and keeping them in seven.

Letters and reports show sales within 60 days of about 15% of whole.

More than usual are going to slaughter, many being held till pasture season in hope of improvement.

Mostly sold because it didn't pay to keep them at present price of products. Many sold to pay grain bills.

More calves are reported in non-dairy sections, and less in dairy counties, indicating that calves are being raised for beef. It is more profitable to feed milk to calves and pigs than sell in market.

Not a county in New England reports enough farm help.

Every county reports help getting practically 25% increase in wages over last year, some counties paying more, few less. Five counties out of 33 reported no shortage of grain. Many farmers in those counties buy in fall by ton in carload lots. Generally, the shortage is very acute.

The effort to raise grain for dairy consumption is general and shows splendid courage. With little help at higher prices 25% of farmers are raising all they can carry on, working long days and selling their products at a loss in every county in New England. It's a lesson in patriotism for cities to contemplate. The cities have no right to expect eight-hour days at profitable wages while farmers work 14 to 16 hours to feed them at a loss.

Most counties have seed available, but prices are almost prohibitive. Few places short of corn, soy beans, etc.

Every county, except one, losing money, and that one "not making much."

Prices desired vary greatly. Probably 7 to 8 cents per quart at country station is about the average.

You need new a

DE LAVAL SEPARATOR NOW

1st If you are still using some gravity or setting process of creaming—

BECAUSE YOUR WASTE IS greatest and quality of product poorest in mid-summer when the milk supply is heaviest.

BECAUSE TIME IS OF GREATEST value on the farm at this season and the time and labor saving of the good separator counts for most.

BECAUSE THE SKIM-MILK IS poorest without a separator in hot weather and often more harmful than helpful to calves.

BECAUSE THE WORK OF A New De Laval Cream Separator is as perfect and its product as superior with one kind of weather as with another.

2nd If you have a very old De Laval or an Inferior separator of any kind—

BECAUSE THE LOSSES OF THE poor separator from incomplete skimming and the tainted product of the hard-to-clean and insanitary separator are the greatest at this season.

BECAUSE OF THE GREAT economy of time at this season in having a separator of ample capacity to do the work so much more quickly,

BECAUSE THE NEW DE LAVAL is so much simpler and more easily handled and cared for than any other, and you can not afford to waste time these busy days "fussing" with a machine that ought to have been thrown on the junk-pile long ago.

BECAUSE THE DE LAVAL SEPARATOR of to-day is just as superior to other separators as the best of other separators to gravity setting, and every feature of De Laval superiority counts for most during the hot summer months.

These are all facts every De Laval local agent is glad of the opportunity to prove to any prospective buyer. If you don't know the nearest De Laval agency simply write the nearest main office, as below.

Best Nerve Specialist in England Was Consulted

But Nervous System Failed to Respond to Treatment Prescribed.

Nervous disorders frequently result from injury to the nerves in accidents or because of the shock to the system.

The writer of this letter was injured in a mix-up with some colts, remained unconscious for three weeks, and in spite of continued treatment in hospital could not obtain restoration of the internal nerves which control the action of the digestive and other vital organs. He travelled to Europe and consulted England's greatest nerve specialist. Relief was only temporary, in spite of many treatments used.

His letter gives the facts briefly and tells how he was finally cured by using Dr. Chase's Nerve Food. Can you imagine any more severe test of this great nerve restorative?

Mr. Henry F. Venn, Cefu Ranch, Malakwa, B.C., writes: "Dr. Chase's Nerve Food has restored my nervous system and given me new health. Having met with a severe accident seven years ago, from which I was unconscious and which left my nerves in a very sore plight, I was treated by doctors galore and consulted one of the greatest nerve specialists in England, but nothing seemed to do me much good. Hypophosphites and, in fact, all and every kind of nerve mixture in almost every form was used, but never with more than temporary benefit.

"But Dr. Chase's Nerve Food has acted very differently, for it has built up my nervous system until I feel like my old self again. If this medicine will do for others what it has done for me, I shall not regret having written this letter. I have recommended the Nerve Food personally to many, and shall always esteem its great restorative value."

Dr. Chase's Nerve Food, 50 cents a box, all dealers, or Edmanson, Bates & Co., Ltd., Toronto.

FARMERS

SHIP YOUR WOOL DIRECT TO US

The Highest Prices Ever Paid for Wool Are Now Being Paid by Us

Mr. Farmer, you can get more money for your wool by sending it direct to us.

In all probability it will come to us anyway at some time, no matter to whom you sell it.

For over thirty years we have been one of the largest buyers of wool in Canada.

We could not continue in business for this length of time if we had not treated our customers fairly and pay top prices.

We send your money the same day as wool is received, only deducing freight or express charges.

We are now paying for wool as follows :

Unwashed fleece, fine....58c to 60c per lb.
Unwashed fleece, coarse, 56c to 58c per lb.
Washed fleece, fine ..... 70c to 72c per lb.
Washed fleece, coarse....68c to 70c per lb.

Ship to-day or write us telling how much wool you have, if washed or unwashed, and breed of sheep clipped from. We will then quote you a straight price and send you shipping tags with full instructions.

LIVE STOCK.

TEMPER IN LIVE STOCK GOOD SIGN

Temper might be likened to fire. It makes a good servant but a bad master. In the animal, as well as the human world, the individual without temper is usually lacking in intelligence, stupid and sluggish. Such animals usually cannot be handled to the best advantage. They cannot be trained to work properly or to submit to human direction of any kind. Those animals which can be made to serve human ends best are animals which possess temper—probably a high degree of temper. But it is in the control of this spirit that there is the greatest possibility of usefulness. The animals most serviceable to man are often those which are most highly strung, and of distinctly nervous temperament.

The vicious, and bad-tempered animal is usually some such animal that has been mismanaged during the formative period of its training. The docile animal may possess as much "fire" and energy, but it has been brought under control, and is subject to the human will as exhibited during any handling that may be necessary. Such an animal is much more valuable about the farm, besides being safe to have around.

Vicious stock are objected to on every side. Besides being a nuisance, they may be decidedly dangerous. In muscular strength the average man is no match for any of the larger farm animals. It is only through control by his higher mentality that he is enabled to attain and retain complete control over brute force. This should be kept in mind all through the problem of farm management. In breaking, training, and handling horses, in stabling and working among the other classes of stock, and in all breeding operations, the problem of control should be remembered. Good stockmen learn to manage their stock without developing viciousness. If viciousness shows they will quickly determine whether it is a result of training, or is hereditary. If it is the latter the breeding of such animals is usually discontinued. If it is the former a little more effort may be put into the correction of the tendency. In all such cases it requires that the man be in full control of himself before the attempt to exercise his right of control on his animals. It is usually through lack of control of self that much of the bad habits and bad tempers result among the stock on the farm.

I. B. Henderson.

IT DOESN'T PAY TO MIX BLOOD IN CROSS-BREEDING

Every now and then one who has spent a good deal of money breeding up his dairy cattle gets the idea that he wants to cross the breed he has with some other that has taken his fancy. In nine cases out of ten the results are disastrous but the fact that on the tenth time the progency may have the desirable characteristics of both breeds will always lead some men to attempt it.

The trouble about this is that if defeats the very object for which men have been working for hundreds of years. Certain types have been developed and kept as pure as possible so they might regularly transmit their desirable points to their progeny. I have seen cross-breeding tried a number of times and I know no man can tell what sort of an animal he is going to get from a certain cross. The mixing of the blood breaks the chain of inheritance and any one may get a "throw-back" that will remind him of what the first wild calf must have looked like. When one makes the cross he breaks the long chain of inherited traits that may reach back for half a thousand years.

PEERLESS PERFECTION
The Fence For Real Protection
gives life time service. Is made of the best Open Hearth steel fence wire, all impurities burned out, all the strength and toughness left in. Makes the fence elastic and springy. Will not snap or break under sudden shocks or quick atmospheric changes. Galvanized to prevent rust and the coating will not flake, peel or chip off. Can be erected over the most hilly and uneven ground, without buckling, snapping or kinking. Every joint is locked together with the well-known "Peerless Lock." The heavy stay wires we use prevent sagging and require only about half as many posts as other fences.
Send for catalog. It also describes our farm gates, poultry fencing and ornamental fencing. Agents nearly everywhere. Agents wanted in unassigned territory.
THE BANWELL-HOXIE WIRE FENCE CO., Ltd.
Winnipeg, Manitoba Hamilton, Ontario

I know a herd of Holsteins that was in a fair way of being ruined by cross-breeding several years ago. The owner reasoned that crossing the Holstein and the Jersey would produce a cow giving the quantity of milk characteristic of the Holstein and retaining the rich qualities of that of the Jersey.

He tried crossing, but it failed to work out very well. He got a few good cows but most of them were far under the standard for either breed and he woke up to the fact that he had so mixed the blood of his herd that he would have to start all over again. The fact that the first cross produced some pretty good animals kept him working along the wrong line longer than he otherwise would. The trouble came in the second generation with a bunch of weedy, nondescript calves that were far from being fit for future use in the dairy.

If those who get good bulls and start to raise better calves would keep at it there would be a big change in the average dairy animal. I have known men to get a first-class sire, keep him a year or two, let him get spoiled and breachy and then sell him for much less than they paid for him. Then they would go back to the mongrels of the neighborhood and all the good results obtained from the use of the good bull would be lost.

This happens again and again. Such men seem to be content to make a temporary change for the better and then slip back in the old ways. To keep going right the pure-bred bull is an absolute necessity at all times. Having got together a few good cows of any one of the noted dairy breeds under no conditions or circumstances breed them to a sire of another breed. If the cows are Holstein breed them to a pure-bred Holstein bull. Mixing the blood will always result in loss of valuable time and money.

PROTECTION FOR SHEEP OWNERS

An act was passed at the last session of the Manitoba legislature designed to protect sheep from the ravages of dogs. It provides that any person may kill any dog which he sees pursuing or wounding any sheep. The owner or occupant of a farm, or his servant, or any member of his family, may kill any dog, found without lawful permission giving tongue and terrifying the sheep in any way. It will also be lawful to kill any dog which may be found straying between sunset and sunrise on any farm on which sheep are kept.

The new law also provides that any person who is the owner of a dog which has within six months previous worried or injured or destroyed any sheep, may be brought before a police magistrate on a complaint made in writing, and, in case of conviction, the police magistrate may make an order for the killing of the dog by the owner. In the event of such an order the dog must be killed within three days, and, in default the magistrate may impose a penalty upon the owner not exceeding $20 and costs, and make a further order for the killing of the dog by a constable or any other peace officer. Such conviction will not act as a bar to any action by the owner or possessor of any sheep for the recovery of damages for injury done to the sheep.

The owner of sheep killed or injured by dogs shall be entitled to recover damages not exceeding $50 from the owner of the dog by an action for damages before a police magistrate. The procedure in cases of this kind will be as nearly as possible in the manner provided by "The Small Debts Recovery Act." All the provisions of the latter act will be made applicable to proceedings under this act for the recovery of damages.

The act further provides that where the owner of sheep killed or injured is unable, after securing conviction before the police magistrate, to collect or realize the amount ordered to be paid, the council of the municipality in which the offender resided at the time of the injury must pay to the owner of the sheep two-thirds of the amount ordered to be paid by the police magistrate.

The council of every rural municipality, town or village, may at the first meeting in each year appoint one or more persons to be known as sheep valuers, whose duty it will be to inspect the injury done to sheep by dogs in cases where the owner of the dog or dogs committing the injury cannot be found. The owner of sheep killed or injured by dogs, the owners of which is not known, may within three months after the killing or injury apply to the council of the municipality for compensation for the injury. If the council is satisfied that he has made diligent search and enquiry to ascertain the owner or keeper of the dog and that he cannot be found, they shall award to the aggrieved party for compensation a sum not exceeding two-thirds of the amount of damage sustained by him, according to the report of the sheep valuer, and the treasurer of the municipality shall pay the amount so awarded.

HANDLING PIGS AFTER WEANING

The strength of the pig when farrowed exerts possibly the greatest effect on the ultimate economy of production. Second only to this point in importance is the influence of wisdom in the feeding and management of the sucking and the weaned pig. More good litters are ruined—and more swine-feeders baffled and discouraged—by improper feeds and feeding and ill-advised methods at the period mentioned, than possibly during any other phase of the pig's existence.

Teach the litter to eat three weeks before weaning. Use a creep which admits the pigs but not the sow. For best results milk products are practically a necessity, with middlings. A few handfuls of dry grain scattered in the bedding ensures the pigs taking exercise. Avoid overfeeding, and make exercise necessary. Gradually increase middlings until weaning. If skim-milk is available, and two litters per year are anticipated, wean at six weeks of age; otherwise, wean at eight weeks.

After weaning start grain feeding as follows: Daily ration for the two or three month pig weighing about fifty pounds; 1 pound of a mixture of barley, 3 parts; shorts, 3 parts; linseed

oil meal, 1 part; with 6 pounds of skim milk daily. Soak for twenty-four hours, and feed. If in pen, add to this some dry oats, scattered in litter. This is not necessary if pigs are on grass paddock. As pigs increase in age, gradually increase the grain to three pounds or more daily, as needed, increasing also the proportion of ground barley or oats in the mixture, until at six mnths of age the ration consists of ground corn or barley, 6 parts; shorts, 3 parts; linseed oil meal, 1 part. Shelter the pasture or paddock-fed pig either with a portable cabin or a light open-sided shed. Avoid, particularly, turning the weaned pig outdoors to a shadeless paddock. Sunburn, skin trouble, temporary and often permanent stunting, ensues. Have natural shade if possible and supply clean, fresh water.

EXTRA PROFIT FROM SELECTED COWS

One remarkably satisfactory result of keeping simple dairy records, yields of milk and cost of feed, is the knowledge gained that cows of good dairy type do repay the cost of extra feed.

One example may be given. Not far from St. Hyacinthe, Quebec, one hundred cows produced 104,854 pounds of milk more during 1916, than one hundred did in 1915. The 1915 records showed that ten were not paying so they were beefed, and again in 1916 eleven were sent to the block, being replaced by better milkers. Better feeding contributed largely to the above noted big increase in milk yield; more corn was fed, more clover and a little higher meal ration.

The value of the extra feed was $605.00, this produced more milk to the value of $1,677.66, so that the extra clear return was $1,072.66, and the cows were in much better condition.

Dairy records help to select good cows and to ensure larger profit.

RINGING A BULL

When a bull is eight months to a year old he should have a ring of 1½ to 2 inches in diameter put in his nose. This ring will be satisfactory until he is two years or older, when it should be replaced by a ring three inches in diameter. Copper or cannon metal are most generally used for rings, but either shows wear in time and care should be exercised to insert a new ring before the old one is worn out.

The ringing of a bull is not a difficult operation, but the animal should be securely tied. A bull punch sold by dealers in such supplies may be used for making the opening, and the ring slipped in as the punch is withdrawn. The insertio nof the ring by using a cannula and trocar is equally satisfactory. The trocar is forced through the cartilage division between the nostrils and withdrawn, leaving the cannula in the opening. One end of the opened ring is then passed through the opening as the cannula is withdrawn. After closing, the ring should be filed and sandpapered smooth at the joint. In some cases a sharp knife or a 43-calibre wad cutter (used for refilling cartridges) may be used, but the other instruments are preferable and will make a better job. In using the wad cutter the hole is made by placing a block of wood on one side of the cartilage to be cut and the cutter on the other side is sruck with a hammer.

The bull's head should be well secured before performing this operation. He should not be handled by the ring until the nose is entirely heale dup and is no longer sore.

FEED FOR CALVES

The following system of raising calves is followed by a successful dairyman with very excellent results:

Remove the dairy calves from the cow at birth. Do not allow them to suck unless weak or unable to drink, or unless the cow's udder is severely caked. Mother's milk for the first four days, at the rate of 8 to 10 pounds divided into three or four feeds, is essential. Feed whole milk for the first ten days, then start replacing part of the same with ski mmilk so that when the calf is one month of age, it may be receiving in two feeds daily, 12 pounds of skim milk plus a tablespoonful of finely ground scalded flax-seed jelly.

At three weeks of age feed a small quantity of whole oats in the manger. Fine hay and clean water might profitably be kept before them from this time on.

During the next fifteen weeks gradually increase the skim milk to 15 or 20 pounds daily. Add to the flax-seed jelly other constituents to make a cream substitute as follows: Finely ground flax 1 part, fine ground oats 2 parts, ground corn 2 parts. Feed in the milk divided into two feeds daily at the rate of one-eighth pound at the start and increase to 1 pound.

Replace the whole oats at four weeks of age with a grain mixture of equal parts bran and rolled or ground oats. Start the calves on one-eighth pound per day and increase gradually to 1½ pounds daily at twenty weeks of age when the skim milk may be gradually cut off and this grain ration increased proportionately.

You can keep the fine natural color in Raspberry Preserves

if you make them with

Lantic Sugar

Long cooking fades raspberries. You can avoid this by using LANTIC SUGAR which dissolves instantly on account of its "FINE" granulation. LANTIC is the best sugar to use for all preserving on account of its purity and high sweetening power. LANTIC is a pure cane sugar equally good for the table, for general cooking and for preserving.

SOW NOT COMING INTO OESTRUM

I have a pure bred Yorkshire sow that I got from the Ottawa Farm Journal about a year ago. She has had one litter of 10 pigs. They have been weaned two weeks. I am feeding the sow three quarts of corn a day and she is in good shape. She is in a small pen and will not come in oestrum. What can I do to bring her around?

I have a male hog. Would she be better with him or by herself. A. H.

Ordinarily a sow that has nursed a little of pigs for 8 or 10 weeks, if a good milker, will be quite thin in flesh even though well fed, and when the pigs are weaned, quickly come in oestrum again. Nature is ever ready to teach us how to do things. Your sow is likely too fat from feeding corn and probably did not give nearly as much milk as she would have done if you had fed her on more nitrogenous food such as oat chop, shorts and oatmeal.

Take away the corn feed, reduce her ration, give her plenty of exervise until is reduced considerably in flesh, then increase her ration and when she begins to gain nicely she will likely come into condition for breeding. It will make little difference whether she is with the hog or not. If both were in a good big yard with a comfortable place to sleep they would get more exercise but had better be separated before you increase the feed. She will show her condition more quickly if running in separate yard along side that of the male.

With all stock the animal selected for breeding should be a good individual and if in addition there is a long line of excellent ancestors upon both sides of his pedigree there will be good reason to expect that he will with considerable fidelity transmit to his progeny the true characteristics of his breed those of his family and those of his individuality.

Purity of breeding on the part of the sire tends to render him prepotent and because of this prepotency it gives him the ability to effect an improvement. The lack of purity of breeding on the dam takes away her power to resist change in the direction desired when mated with pure-bred sire; consequently dams of mixed breeding are excellent material upon which to commence the work of upgrading so far as blood elements are concerned.

Far more effective than Sticky Fly Catchers. Clean to handle. Sold by Druggists and Grocers everywhere.

THE HORSE

GROWING PRIZE-WINNING DRAFT FOALS

By Professor M. G. Thornburg, Iowa Agricultural College

To produce prize winning foals three things are necessary. First, the colt must be well bred; second, must be well developed, and third, must be shown in a fit and attractive manner.

Exhibitors should begin to make plans long before the date of the show. In fact, the right time to start is when the sire of the colt is selected. The type depends on the colt's parents. It can be little influenced by feeding and therefore the selection of the sire is very important. In choosing the sire, select one that will "nick" well with the mare. Look to his colts and see if they are the right type. Prize winners have been produced from haphazard matings, but more prize winners have been produced by careful selection and matings.

From the show ring standpoint, it is well to have the colt come early. February and March foals have big advantage in scale over the colts that come in May and June. Size in the show ring is important; few judges take into consideration as much as they should the difference in age of the colts. It is hard to turn down a colt two to three hundred pounds heavier, even if there is a difference in their ages. It is practically impossible for the judge to determine the exact difference in age, so he invariably gives the larger colt the preference.

Feeding for the development of the colt should start long before it is dropped, in giving its mother the proper care and feed to produce a strong and vigorous foal. For best results it is absolutely necessary for the brood mare to have proper exercise while carrying a foal. Judicious work is perhaps the best and easiest way to furnish the exercise. When it is not possible to work her moderately every day, the next best course it to allow her plenty of range in the pasture.

Brood mares should also be properly fed. Experiments tell us that the size and vigor of pigs are influenced by the feed given the sow. The same principles of nutrition should hold true with colts. Most brood mares do not get enough oats, bran, oil meal, clover or alfalfa, but oftentimes are allowed to subsist on straw for weeks at a time. Colts from mares that are not fed on feeds rich in muscle and bone building materials are handicapped from the very start and with the best of care and feeding cannot compete with colts that are strong and vigorous when born.

During the nursing period the mother should be fed to produce a good supply of milk, especially after the colt is a few weeks old. Nothing can take the place of the mother's milk to keep the colt in a thrifty and growing condition. A few showmen add cow's milk to the colt's ration to keep them in bloom. Care should be taken not to over-feed on cow's milk as it is likely to cause scours if fed too heavy. It should be fed in small amounts, quite often, at about the same temperature as the mare's milk. Idle mares that have the run of a good pasture, with an occasional feed of oats, should produce plenty of milk. The mares that have to work hard each day are apt to be short on milk. They should be catered to in feeding, being given plenty of oats and bran, with clover or alfalfa hay and a run on the pasture at nights and on idle days. There is no feed so good as grass to produce milk.

Feed, exercise and comfort are the requirements for rapid and early growth. The foal needs grain in addition to the dams milk and grass. By the time he is a month old he should be given an additional grain feed in a separate box from that of his mother. A little oat meal is the safest feed to start him on, substituting later with oats and bran. Let him have all the clover and alfalfa hay he cares for. If he is running with the dam in the field a creep should be fixed up where he can get grain whenever he wants it. The creep should be placed near the shade or shelter where the horses usually rest or stand to fight flies.

The colt permitted to run with his mother in pasture will usually develop fastest, but where flies are bad it pays to keep them in the barn during the day, and turn to the pasture at night. When the mother is at work make the colt comfortable in a roomy, cool box stall, or if there is a paddock adjacent where he can exercise, so much the better. Don't let him wear himself out following the mother in the field. It is practically impossible to over-feed a foal if the feed is selected for growth and development. Cater to his appetite and keep him in good condition. Many exhibitors give excuses for their colts being thin by saying: "They are just in good growing condition." In reality, a colt that is growing as fast as it should invariably carries considerable fat—at least enough to hide the ribs and angle of its frame. To win in the show ring, it should be just fat enough to have a pleasing appearance. There is no danger of getting the colt over-fat if it has plenty of good exercise.

Exercise is essential to growth. Colts that are shut up in the barn and stuffed with feed are apt to go bad in their legs. Exercise also aids in digestion and helps to keep the foal in a thrifty condition. Give the colt a paddock, or, better, a small pasture where he can eat and exercise when his mother is working, but be sure the fences are in good shape so he cannot get hurt. He will be happier and more comfortable if he has another colt as a companion. If the mother is not at work, the foal will get plenty of exercise with her in the pasture.

The care of the colt's feet is another important thing to look to. Neglect has caused many deformities. By the time the colt is about two months old the feet should be examined carefully with the colt standing correctly on a level floor; also observe the action at both a walk and trot. Then rasp the roof wall so as to correct any defects you notice. The hoof wall should be even on all sides. Many times the toes should be shortened or the heel reduced so as to help the set of legs. The sharp edges of the hoof should be rasped off to keep the wall from chipping. Do not pare down the frog or cut the bases; the outer wall is all that should be touched and this only sparingly with a rasp. Shoes may be put on before showing and will increase the action and help to correct a faulty action if put on by an expert horse shoer. They will also make the colt's feet look larger. The shoes should be on long enough before the show for the colt to get used to them and not appear awkward.

From the very first, the colt should have plenty of training and grooming, teach him to lead and stand correctly. All judges will insist on the colt's being moved and the colt that leads up nicely will make a more favorable impression on the judges than those that have to be dragged or pushed along. A little training in leading and showing will help wonderfully in the colt's making a good appearance in the show ring.

The colt should be well groomed and perfectly cleaned when taken into the judging ring and to add to the appearance, decoration could be put in the mane, and tail. An "Aberdeen plait" in the name, with three or four roses is good. The "Herring bone" is the proper thing for the tail. Don't over do by putting in a too heavy decoration, and never disfigure the appearance of the colt by trimming his foretop and main.

All exhibitors of horses should train their colts to lead well before putting them into the show ring in classes in which they have to be shown on the rein. Ten or fifteen minutes spent daily for ten days in leading lessons will usually get a colt to go handily. For ordinary purposes it is not necessary to use the long rein of the expert nagsman as when showing a hackney, but the rein may be held about a foot from the head, and loosely, but just nagging sufficiently to keep the head in position and regulate the pace.

The leader should run along and avoid looking at his charge, for if he looks at him, he will go sideways, if possible, or not lead up. The off side of the horse should be along side of a wall or fence to make him go straight; a lane is a good place as the offside can be kept towards the fence going both ways. A run of fifty to seventy-five yards is ample and a man should be at either end to stir the colt up, with the whip, so as to make him lead up freely. If nobody is available for that purpose, the nagsman can carry a long straight whip in his left hand, with the point of it directed towards the hocks.

FARM HORSE HEALTH

Azoturia and colic are uncommon diseases among farm horses, considering the large numbers of horses in the country. Prevention of azoturia is largely due to the common custom of turning work horses out to pasture or in a lot when idle. Prevention of colic is perhaps mainly due to the good quality of hay and grain selected for horses on the farm.

If farm horses were stabled when idle azoturia would be a common disease. In cities it frequently occurs as Monday morning sickness. The veterinarians recommend as a preventive that horses be fed only about half the usual grain allowance when standing idle in the stable. The farmer usually turns the idle horses out after breakfast and they get no grain at noon. Then they are free to exercise and that of itself prevents the disturbance of nutritive functions which would result in azoturia. On this account many farmers do better than they know. They should keep in mind the fact that one or two days of full feeding of grain to a horse that has been hard-worked up to that time, and then is allowed to stand in the stable, is likely to cause sickness and probably death when the horse is taken out again to work.

Fortunately a farmer has the opportunity to select the best hay, oats and corn that he raises, and feed these to his horses. That helps greatly in keeping the digestive system in good working order. Perhaps one of the mistakes most frequently made is in feed-

ing oats to work horses that are turned out on grass at night. Corn is safer to feed with grass. Especially if grass or clover is of luxuriant growth the oats seem to predispose to colic. The horse pasture is usually near the barn and is small, and it is so very handy in which to turn the calves or any other stock that must be brought up to the barn ayain, that the vrass then is usually kept short. The horses must pick longer to get a fill and that prevents injurious results that might otherwise follow.

KEEPING SHOULDERS CLEAN AND SOUND

A man complained that he had too many sore-shouldered horses and asked his friends to take a look at them. The collars fitted well enough. In fact, some of them were rather on the snug side; most of them were new and all were dirty. A visit to the barn revealed two or three old brushes rather devoid of bristles and some old currycombs. There were no rubrags, no sponges, nothing to encourage teamsters to clean their horses. One of the teams was much cleaner than any of the others. And no wonder; when that teamster returned he went to his dufflebag and produced everything necessary to put a racehorse in shape, from a sponge to a rubrag, and the rubrags were clean. The other men seemed anxious enough. They took turns with the derelict currycombs and brushes, but they seemed quite ignorant of the uses of the rubrag and did not even tear up gunnysacks. The result was that the horses' shoulders were left dirty, and some greasy dope having been applied for several days the sores had gathered a maximum of dire. Proper tools were issued and dusting powder substituted for the unguentum, which the foreman pronounced "Annie Guentum." Within a week the shoulders that were not entirely healed were at least on the high way to recovery. The men were not only using the rubrags in the stable, but were carrying one with them to rub off the horses' shoulders in the field when they became sweaty and dirty. Owning $200 horses and allowing their shoulders to become sore from lack of proper cleaning conveniences is one of those things that probably no man understands except the one who practices it.—L. Ogilvy in Breeders' Gazette.

OATS AND RAPE FOR PASTURE

"I have read with interest your various articles on pastures for hogs. I plan to sow a small field with a mixture of rape and oats. How much per acre should I sow, and how many pigs should it carry per acre in summer?"

On rich ground, rape will furnish an immense amount of pasture, but on poor ground it does not amount to much. On ordinarily good ground, in the average season, we would expect an acre of rape and oats to support, during the season, about three sows and eighteen spring pigs. This is on the assumption that a fairly heavy grain ration is fed, and that the rape and oats are allowed to get a good start in the spring. It ordinarily seems best to allow the rape to get at least ten inches high before beginning to pasture. Also, it is best to give it a rest when it is reduced to only four or five leaves per stalk. Sow as early as possible at the rate of six pecks of oats and five pounds of rape per acre.

Don't let the cutworms destroy the products of your toil in the garden. They can be poisoned. Mix 25 pounds bran, 1 pound paris green and 3 finely chopped oranges and lemons. Add enough cheap molasses to make a stiff dough. Distribute this over the infested garden or field just a little near each plant. The best time to put it out is in the evening.

OVER 600 Imperial tank stations dot the Prairies and the Eastern provinces, so located as to give the quickest service to the farmer. There is one near you. The agent at that station will give you courteous, prompt attention, will tell you the right oil for each machine on your farm.

All our oils are supplied in steel barrels and steel half-barrels — convenient, economical. No waste. You use every drop you pay for.

AN OIL FOR EVERY FARM MACHINE

DIARRHOEA

WAS SO BAD.

Thought She Would Lose Child.

During the hot weather young children are very much subject to diarrhoea, in fact, more so than adults, on account of the more delicate construction of their constitution. It behooves every mother to look after her children on the first sign of any looseness of the bowels, for if they do not some serious bowel trouble such as diarrhoea, dysentery. cholera infantum, cholera morbus, summer complaint, etc., is liable to follow, and they will perhaps, loose their little one by not taking the precaution to check this looseness of the bowels by using Dr. Fowler's Extract of Wild Strawberry.

Mrs. R. J. Hillis, St. Mary's, Ont., writes: "My little girl was so bad with diarrhoea the doctor could not cure her, and we were sure we were going to lose her. A friend of mine told me to use Dr. Fowler's Extract of Wild Strawberry, so I sent for a bottle right away, and by the time I had given her one bottle she was able to sit up, and before I had the second bottle used she was cured. I tell everybody about this sure cure. The price is 35c. a bottle, but it is well worth it.

It is 11 years since I first tried it, and will always keep it on hand. It is good for old and young alike."

"Dr. Fowler's" has been on the market for the past 72 years, so if you want to be on the safe side be sure and see that you get "Dr. Fowler's" when you ask for it.

The genuine is manufactured only by The T. Milburn Co., Limited, Toronto, Ont.

RELIEF AT LAST

I want to help you if you are suffering from bleeding, itching, blind or protruding Piles. I can tell you how, in your own home and without anyone's assistance, you can apply the best of all treatments.

PILES TREATED AT HOME

I promise to send you a FREE trial of the new absorption treatment, and references from your own locality if you will but write and ask. I assure you of immediate relief. Send no money, but tell others of this offer.

POULTRY.

THE LICE AND MITE TROUBLE WITH CHICKS

The development and growth of the young chick can be greatly hindered by the presence of lice and mites. They will sap away its life and even if it is able to withstand them, will be weaker and undeniably tardy in its growth and maturity.

There is considerable difference in the treatment for chicken lice and chicken mites. The lice do not stay on the coop or chicken house, but on the chicken itself, so that the disinfectant must be applied directly to the chicken in the form of a lice powder, dip or spray; while the chicken mite stays in the cracks about the coop or chicken house or in crevices in the roosts or nests ready to come out at night and go onto the body of the chicken. To effectually rid the premises of mites, it is necessary to apply the disinfectant preparation in the form of a spray over the whole inside of the chicken house or coop and in all the cracks and crevices and over all the roosts, supports, nest boxes and dripping boards. Good results are to be had in killing mites by spraying with creosote oil and kerosene. This readily soaks into the cracks and crevices and destroys the mite as soon as it comes in contact with them. Crude carbolic acid and crude petroleum can also be used to good advantage.

As a home remedy for body and head lice, use a mixture made up of three tablespoonfuls of lard, one teaspoonful of kerosene and ten drops of some disinfectant mixed warm. Apply a few drops of this mixture to the head, around the vent and under each wing of the chicken. This will rid them of the lice.

Cleanliness is a very important factor in keeping the chicks free from mites and lice. The coops, hen-houses and roosts should be kept clean and plenty of whitewash used. It not only improves their quarters but adds very greatly to the appearance of the chicken yards. Move the coops for the young chickens on to new ground about every two weeks, and locate close to some young clover or fresh grass land.—P. H. Eaton.

WHY KEEP THE ROOSTER

In the matter of egg production there is only one time in the year when the male bird is a desirable creature on the poultry plant. Chicks are necessary to keep the flock going from year to year, and for this reason a certain amount of breeding work must be carried on each spring season. Then and then only is the male bird necessary. Except during the breeding season the male should be kept away from the females. He may be considered a nuisance, for he is not necessary and is often harmful. As far as the growing stock is concerned, pullets will grow better if the cockerels are separated from them as soon as the sexes can be distinguished. The cockerels will grow better, too, and they will make better roosters and better breeders. The pullets will develop into better layers and, therefore, it is profitable to select the growing stock early in the season. Throughout the summer months the hens will lay better if the cock birds are not left with them. Furthermore, where males are kept away from the laying flocks the eggs produced are infertile.

In an effort to control lice do not dust birds and grease them at the same time. Dust the birds with Persian insect powder, which is a very fine dust that will clog the breathing pores of the pests.

When chicks are brooded with hens it is frequently the custom to feed the birds on boards in front of the brood crops. Then the boards and coops are moved occasionally and it may expose mould which has been growing on the ground under the boards. If the chicks scratch in this mould or eat any of it the result will be sickness so it will pay to clean off the mouldy soil if any of the fungous growth are noted around the brood coops.

Give each of Your Children a War Savings Certificate.

LET them feel that they are Canada's partners — that they have each a definite share in the stern struggle—the certain victory—and the free and glorious future.

Encourage them to save and buy Certificates themselves! You'll be developing their patriotism, their thrift and their business sense—for Canadian War Savings Certificates offer absolute security and excellent interest return. More important still, you will be guaranteeing their future, for every dollar lent to Canada helps win the war.

For each $21.50, $43 or $86 lent now, the Government issues a Certificate, payable in three years, for $25, $50 or $100. This means that interest is added at over 5% per annum. Certificates may be purchased at any Bank or Money Order Post Office.

For the sake of Canada and your children, save and invest in War Savings Certificates.

The National Service Board of Canada,

WEED OUT THE MALE BIRDS

(Experimental Farms Note)

The worker bees put their house in order by killing off all the mal ebees as soon as their services are no longer required. What a great benefit it would be to the poultry producer and the poultry product consumer if the hens of the flock would likewise dispose of the male birds in those flocks that are indifferently managed. The worker bee permits no star boarder to loaf around and consumo the product of her labour. The hen is not like the bee in asserting her rights. If she were, then her verdict would be, "Rooster you must die."

There are over two million five hundred thousand roosters of the various breeds of chickens kept for breeding purposes by the people of our country. Of this vast army perhaps one hundred enough as individuals and in breeding and fifty thousand have a right to live for another year of service. One hundred and fifty thousand may be good enough as individuals and in breeding to be used in the increase of their kind. What of the two million three hundred and fifty thousand that are usually permitted to live, birds that consume feed, worry the hens and reduce the quality of market eggs?

The function of the rooster is to develop and distribute germ cells, during a short period of three months, February, March and April. These germ cells should be distributed only to such egg-laying individuals as are desired to perpetuate the breed. The germ cell is a living organism capable of starting a chain of development and here is where the mischief lies if they are distributed where they do not serve their proper function in race perpetuation.

The function of the modern hen is to produce eggs, ten percent of which may be desired for the increase of the breed and the remaining ninety per cent for human food. Nine eggs are used for human food where but one is used for hatching. Only one-tenth of the eggs that a hen lays require fertili ation. Why fertilize the nine-tenths of the product that is used for human food? The addiiion of a living germ cell to an egg that is produced for human food does not add anything to its value and may set up a chain of embryo development that will make the egg quite unfit for human food.

Eggs gathered from flocks where the roosters are permitted to run after the hatching season is over, are not desirable for storage. They are not desirable in the pantry during periods of warm weather as high temperatures will start incubation. Eggs in the first stage of decay are not desirable for human food.

It is an easy matter to prevent the fertilization of eggs. If the male bird is just an ordinary one an axe and a block of wood will prevent further mischief. If the male bird is possessed of such merit as would warrant his being boarded for a year to be used in the next season's breeding operations, then give him an enclosure of his own and see that he stays in it.

The cost of the feed consumed by an ordinary rooster is about twenty cents per month. Can you afford it? If you keep poultry with profit as your object, can you afford to keep a star boarder for nine months and perhaps have him doing mischief all tho time?

The two million, three hundred and fifty thousand odd, unnecessary male birds are costing the country about three and a half million dollars per year while enjoying life. These unnecessary birds are at the same time doing about ten million dollars damage to the egg-producing business. If every person owing a rooster would manage him as a male bird should be managed, the poultry industry would be benefitted by additional profits many million of dollars.

FROST & WOOD BINDER

This year of all years you must have machinery on which you can depend—no matter what your field conditions are at harvest time.

The Frost & Wood Binder will harvest any crop—big, medium or light—in perfect shape.

It is light in draft and so easy to run that inexperienced help or any boy able to handle a team can operate it.

80 Years of Experience in Its Make-up

Sure Cutting--Sure Tying--Easy Levers--No Choking or Threshing

The high quality materials of which the Frost & Wood Binder is built—its design—its light draft and its satisfactory work are known and appreciated by every user. Don't waste valuable time and more valuable crop this year "fussing" with an old machine, when you can be sure of steady cutting and clean work with a new Frost & Wood Binder. The investment is small compared to the returns you will receive. Talk it over with our nearest agent.

Let us send you the new F. & W. Binder folder or get it from the nearest Frost & Wood Agent.

LAYING HENS INDICATED BY OUTWARD SIGNS

General use of the trap nest during the past few years has brought to light many supposed correlations between external characteristics and ability to produce large numbers of eggs. As a result quite a few systems of selecting laying hens have been worked out These external indications of production are of some value to the close observer. but other conditions have a decided influence on the prominence or absence of some of these external characteristics. This is especially true in reference to the amount of yellow pigment in the shanks and ear lobs of White Leghorns and similar breeds.

The theory is that the heavy layers gradually utilize the bulk of the yellow pigment, thus changing the color of the shanks and ear lobes from a rich to a pale yellow or whitish color. In applying this theory those with the least indications of yellow pigment in the shanks, ear lobes, skin and plumage would be chosen. Actual applications bring out some interesting facts.

In a certain test it was found that rich orange-colored shanks did not fade out nearly so fast as light lemon-colored shanks. Some birds had pale shanks after producing twenty-five eggs, while others had yellow shanks after laying more than 150 eggs. Some birds had white ear lobes before they began to lay. Clearly, the absence of yellow pigment may or may not be indicative of heavy production.

These exceptions to the rule, however, do not necessarily imply that the results of its application are guesswork or luck. Given certain conditions, the application of the theory may be of considerable value to the poultry keeper. As a general rule, the absence of yellow pigment in hens that normally have yellow shanks and ear lobes is a fairly accurate indication of past heavy production, provided the birds are of good vitality, have been fed on yellow corn and supplied with good grass range or runs.

The time of molting is another fairly reliable external indication of heavy production. Analyses of trap-nest data indicate that the heavy layers are generally late molters. In a recent study the careful application of this theory showed that none of the birds that were halfway through the molt by October first were high producers, and that only a small percentage of the late molters were low producers.

Another point of interest observed was that the late molters molted late regardless of whether it was the first, second, third or fourth year of production. It was also noticed that late molters molted rapidly and began laying almost as soon as those molting earlier.

Shape or conformation, health and vitality as indicated by the condition of the comb and other parts of the body, activity, ability to consume large quantities of feed and size of the abdomen are other points round which theories of production have been built.

The application of these theories in practice is difficult and unsatisfactory, largely because of the inconsistency of the results obtained. A bird may have a long back, a full abdomen that gives a wedge-shaped appearance, be a healthy, active disposition, and still turn out to be a very ordinary producer. On the other hand, a bird more or less the opposite of this type may prove to be a very good performer.

My own observations have been that the bulk of the high producers are about the scrawniest-looking birds in the flock. Some have short backs and wry tails; others have long backs; some are big and some are small; some have large combs and some have small combs; some are of the so-called wedge shape and others seem to be built on an entirely different plan; and we can continue to compare the different points until we decide that there is as yet no such thing as a consistent egg type in birds of high production.

It is not my intention to convey the thought that these points are of no value in selecting heavy producers; for when it is possible to find them in early producers, late molters or in birds usually having yellow shanks and ear lobes that have become pale because of heavy production, we have all the more reason to believe that such individuals are exceptional performers.

Of all the external indications of heavy production that may be observed with some degree of accuracy without the aid of the trap nest, the most valuable are early production during the pullet year, late molting, and the absence of yellow pigment in the shanks, ear lobes and plumage of birds normally having yellow shanks, when conditions have been such as to maintain the supply of yellow pigment. It is possible, without any great amount of trouble, to observe these indications and, when they are carefully observed and applied in the improvement of the flock, substantial progress will unquestionably be made.—C. L. Opperman in O. V. J.

The excessive feeding of cabbage is believed to have caused chicken pox and one point which seems to prove that contention is the fact that there has been scarcely any chicken pox this year and also very few cabbages used for chicken feed. Mangels are a very good green feed and considered far safer than cabbages by some poultrymen.

FOR HOME AND COUNTRY

Subjects relating to household science and all that stands for better homes and communities will be published on this page. The editors, Misses Saunders and Winter, of Fredericton, N. B., solicite your assistance in making this page a success and will be glad to publish tested recipes, household discoveries and other articles useful to the homemaker and women's organizations.

HER BROTHERS FARM

The rain was falling heavily when Hope Justin alighted from the train at the little station of Poplarville. It did not take her many minutes to examine the crowd and to ascertain that her brother was not in it. "I wonder what can be keeping him?" she thought to herself. "Surely my letter could not have been delayed."

Just then a hand was laid on her shoulder, and a voice which she knew so well said, "Hope, I'm so glad you've come." "Why Laurence, I was afraid you weren't here," she exclaimed.

Greetings were soon over, for it was not pleasant standing out in the rain. "Come," said the man, "my horse and buggy are just over here." As he tucked his sister in he said, "Now, Hope, I know you are just longing to ask dozens of questions, but not a word until we get home." All right," she replied, with a faint little laugh, "I suppose I shall have to obey."

As they drove slowly along the street in front of the few buildings from whose windows the light streamed, Hope looked earnestly at the man at her side. Surely this grave, quiet man was not the gay, boyish Laurence of one year ago.

"Here we are," said Laurence at last, as he sprang from the buggy. Hope was startled, for she had been almost asleep, but, with her brother's aid, she managed to clamber out. "Come right in," he said, as he led the way to the house. As he opened the door he said, "I'm afraid you'll find things in pretty bad shape here, but this batching is just awful!" After showing her where the provisions were, he went out to see to the horse, leaving her to prepare some supper.

The next morning the sun was shining brightly, and the whole world looked fresh and gay. When breakfast was over and Laurence had gone to work, Hope stood in the doorway and looked about her. The three children were playing happily in the yard. It seemed to them that a fairy had come straight from fairyland to them. Of course they had known that she was coming, but they had not thought much about it—they had too many childish troubles of their own to bother about anything else. The two older ones had welcomed her at once, but Master Harry was doubtful. He was very young when the family went to visit at Milford, and consequently did not remember his aunt. That morning, when his father brought him home from Mrs. Read's, where the children had stayed while Mr. Justin went to town, he had half a mind to revolt, and have nothing to do whatever with the strange lady; but something in her brown eyes, together with a piece of cake which she held in her hand, proved too much for that young gentleman. He at once joined forces with her, and from that day forward they were the very best of chums.

"I believe," said Hope to herself, as she surveyed the tumble-down condition of everything about her, "that this farm could be made into a beautiful place. Laurence has never bothered much about the look of things. He has been too busy trying to make money; but, perhaps, if I see about fixing things up inside, he will try to make things look better outside. I think I'll just have a look around right away."

The house contained five rooms, but two of them were pretty well filled with Laurence's tools, some large packing boxes, and everything, in fact, that was not wanted in any other part of the house. Hope saw at once that a very comfortable little home could be fixed up. Edna, her sister-in-law, had never spent much time making things look cosy and homelike. The days always seemed far too short for her to do what really had to be done. It was the same with Laurence. He never spent any time making his farm look neat and attractive. What wasn't really necessary was never done.

"We will see," said the girl aloud, "but I really must do some washing and baking to-day, so I shall have to leave my house cleaning for another day."

Just when they had finished eating dinner, which, by the way, was an excellent one, a neighbor rode up to the door and handed Laurence a letter. Anxiously he tore it open and read it; then he exclaimed, "Hope, the doctors at the hospital feel quite sure that by next fall Edna can come home!"

Of course, this caused great excitement all around. When her brother could really give a thought to common everyday matters, Hope said, "Laurence, don't you think that it would be a good idea to fix things up and make your farm more beautiful? A coat of paint applied to the house, barn, and hen-house would help wonderfully, and you know your fences are really badly in need of mending. You told me that Edna did not seem very contented here, and that you sometimes thought you would have to sell out and go to town to live. Why not make this place more pleasant and homelike instead? To tell you the truth, I do not blame Edna for being discontented, for it must seem dreary to her after the beautiful home she left to come here. I am sure that if some changes were made, anyone could love this place. The trees and the little brook down by the road are just what I have always longed for." After a moment's pause, she said, "I have a plan; may I present it?" Laurence nodded, so she continued, "Why not plant grass and flowers out at the front where you planted the potatoes last year? It would help more than you would think, for you could put a door in the room where Dot and I sleep, and make a nice comfortable front room out of it. The attic room can be made into a bedroom for us. I know that it would do splendidly."

Laurence stood looking thoughtfully at the floor for some minutes, then he said, "Well, Sis, I guess you're right, and we'll try to make things a bit better around here."

In due time the room in which Hope and Dot had slept, and the attic room were cleared. Hope did this while her brother was plowing a place for the lawn and another for a garden. When everything had been moved from the front-room-to-be, the walls and ceiling were tinted a deep cream. New muslin curtains with a pink rose border were hung at the windows, and Hope got out her stencilling outfit and did a border around the room to match the border on the curtains. An inexpensive carpet with brown and rose colorings was bought for the floor, and Hope added two large wicker chairs, a little table, and a couch, while Laurence made a bookcase to stand in one corner.

The rest of the house was whitewashed, and plain white muslin curtains were put on all the windows. The wide porch on the south side of the house was boarded up and converted into a kitchen. Although none of the other rooms were quite as pretty as the "new room," as the children called it, yet they were all beautifully neat and clean. Hope sent home for some pictures, and when they came, they added a great deal to the charm of the rooms.

At length the time for planting the garden arrived. Then came fun for all. While Laurence worked in the fields, Hope worked in the garden. With her help each child planted a little flower garden, and many were the happy hours afterward spent in them.

After seeding, Laurence went to work with a will to make his farm look better. The house, barn and henhouse were all painted, and the fences repaired. A new picket fence was made around the lawn, and a red brick walk extended from the gate to th walk extended from the gate to the front porch. Laurence found many little things, too numerous to mention, to be done, but, small though they were, they all helped to make his home more beautiful.

On the first of August word came that Edna had made wonderful progress, and would be home in a week. To Laurence and the children that week seemed the longest one in their lives, but to Hope, anxious as she was to see her sister-in-law, it went all too quickly. There were so many things to be done in the house, and only one to do them. Of course Dot was anxious to help, but little girls of eight, although their intentions are good, are very apt to get in the way, in their efforts to be useful. In order to have a clear field for operations, Hope tried to keep the children busy gathering eggs, looking after the little ducks and chickens, and weeding their flower gardens.

At last the week was nded and Edna came home. As she and Laurence drove along the road that morning, she asked many questions; but husband had pledged himself to keep silent, so Edna got little information. At last, telling him that he had developed into a staid, taciturn old bachelor in her absence, she gave up, and contented herself with looking about her

at the wonders which Mother Nature had wrought since she last drove along that road. As they turned a corner, Edna gave a cry of surprise and joy. "Oh, Laurence, how lovely "

The scene that met her eyes might well give rise to those words. There, basking in the morning sunshine, stood the little white and green house, over whose front porch climbed hops and wild cucumber vine. In front, encircled by the white picket fence, lay the lawn, like a soft, green carpet. On either side of the porch steps a tall golden glow bloomed in rich profusion, while on both sides of the walk a double row of pansies and nasturtiums lent their beauty to the scene. Along the south side of the fence sweet peas and baby's breath mingled in perfect harmony, and on the west, between the trees on either side of the gate, bright poppies and sweet white daisies nodded their heads. On the north a large garden of mixed flowers smiled their welcome. Beyond the house, with a background of lovely trees, stood the barn and hen-house, both in their new red coats.

"Why, it doesn't look like the same place " gasped Edna.

Just then the front door opened, and out came Hope and the three children. What a time there was, then! It seemed that the children could not possibly make their tongues work quickly enough. They all talked at once, and each tried to tell something different. Poor, bewildered Edna begged for a breathing space, and Hope, with some difficulty, chased them off to gather the eggs.

While they were gone, Edna had time to look around her a little. "Oh," she said, "I feel as if I can rest here, it's all so lovely and fresh." Just then Laurence and the children came in for dinner.

That evening, when they had all gathered on the front porch to enjoy the cool stillness of the evening, Edna said: "Hope, Laurence and I both want to thank you for what you have done to help make our home what it is now. I feel as if I never want to leave ti again. There is now no danger of me wanting to go to town to live. You have been so good and unselfish to stay here all this while. Why, I don't know what would have become of Laurence and our kiddies if it had not been for you." I don't know, either," came earnestly from the steps where Laurence sat.

"We would love to have you stay with us," continued Edna, "but you have been here for so long that you must be getting lonely for home. If you feel that you would like to go, just say so."

"Oh no, Auntie Hope, don't go away," came in a chorus from various parts of the porch. "No," said Hope, rising as she spoke, "I shall stay with you until you are quite well and strong again. I have never once been homesick since I came. I get letters from mother and father every week, and although I sometimes feel that I should like to see them, yet I am quite happy and contented here, so please don't try to pack me off home for a while. Good night everyone," she said with a little laugh, as she disappeared through the door, and they heard her singing softly to herself as she made her way up the stairs to her little attic room. "What a dear, good girl she is," breathed Edna, lovingly. "Indeed she is," answered Laurence, softly.

SAVE THE VEGETABLE WATER

One of the economy suggestions recently made was to save the water in which vegetables had been boiled. "This water contains nutritious juices," it was stated, "and makes very good soups and sauces—only a slight economy, but very worth while when we consider what the women of other countries have done to solve their food problems."

This is really a very good suggestion and one that the average French housewife would readily understand; for the French housewife has for long made use of vegetable water to enrich sauces and soups. But from that above-quoted suggestion, what could the average housewife do? There is nothing in the appearance or taste of the water in which carrots or onions or even priceless potatoes have been boiled to suggest anything very delectable. Still we know the goodness is there. Food chemists even assure us that very important minerals are extracted from the vegetable in the boiling process and it is all the more necessary, therefore, that we should make use of this vegetable water. Well, here is a suggestion or so.

Suppose you have been cooking beans of any kind. Save the water. And when the beans come from the table in the vegetable dish you will be sure to have some left over. Return these to the bean water and simmer them gently. When well cooked to pieces rub the beans through a sieve as much as possible. Let this liquor cool and when you are making ready next night's dinner, place a large tablespoonful of flour in a saucepan with a teaspoonful of butter. Rub together and then mix with it a half cupful of milk. Place over the fire and stir till it thickens. Then gradually add the juice and puree from the beans. Season with pepper and salt. If you have a little beef or lamb gravy left on hand add it to the soup. Or, if you wish, add a teaspoonful of soup extract. If you had a few bones—beef or lamb—you might have boiled them with the beans when simmering them, in order to get the meat flavor; however the meat flavour is really not necessary.

Here is a way to make use of vegetable liquor in brown sauce that is delicious as a dressing for macaroni or rice when served as a potato substitute. Place a finely cut up onion in a saucepan and fry brown in a tablespoonful of flour and allow it to brown slightly without burning. Now add a cup and a half of vegetable water and cook it till it thickens slightly. Season to taste.

The addition of a very little parsley or other fresh herbs improves the flavor. A teaspoonful of ketchup added to a sauce made from vegetable water adds zest and is especially good when served with macaroni.

THE SUMMER STOVE

This advice is not for those who live in the inconvenient city with its dust, noise, confusion and gas ranges. No, take your ease, enjoy your comforts along with annoyances country people never have and envy the latter more than ever for the new oil stoves are almost equal to some gas ranges that are considered mighty fine.

The oven built on fireless cooker principles that cook by retained heat are one new thing that makes oil-stove cookery simple and interesting. By thoughtful planning a selection of foods can be cooked so that every particle of heat from the moment the fire is lighted until the oven is cooled, can be utilized. Of course, this applies to any oven, but as I told you, this is for those who use kerosene for kitchen fuel. When cakes are mixed, ready for baking, place them in a cool oven and they will rise as the heat increases. Gingerbread and all rich mixtures are better flavored by long baking than if put directly into a hot oven. When the cakes are out put in the roast, pudding, pies or such foods as need high heat. Reduce the heat when the articles are almost cooked and

Eureka Potato Digger

Gets the Potatoes and separates where other diggers cannot

A strong statement, but an actual experience many times, saving growers more than the cost of the Digger. Ask us for the proof.

The Eureka elevator and duplex shaker provide more separation than other diggers. Large wheels and main gears supply ample power. Mostly malleable and steel. Running frequent breakage and lost time. Growers report digging 80 or more acres without repairs. High clearance over shovel prevents weeds and vines bunching. Has vine-turner attachment.

6-ft. and 7-ft. sizes; several styles.

SUFFERED TERRIBLY

WITH HEART AND NERVES.

WOULD WAKE UP SMOTHERING.

Milburn's Heart and Nerve Pills Cured Her.

Mrs. A. M. Powell, Norval, Ont., writes: "I cannot speak too highly of Milburn's Heart and Nerve Pills. I suffered for five years with my heart and nerves, but the last two years I have suffered terribly. If I went to bed I would wake up as if I was smothering. I did not get one night's sleep out of seven. I got so very weak that the doctor was called in, and he said it was my heart, and that I must take great care of myself. I saw your advertisement in your almanac for Milburn's Heart and Nerve Pills, and said I would try them. I have only taken two boxes of them and I feel a new woman. I will recommend them to anyone afflicted with heart trouble."

Milburn's Heart and Nerve Pills are 50c. per box, at all dealers or mailed direct on receipt of price by the T. Milburn Co., Limited, Toronto, Ont.

put in the vegetables that can be roasted or baked. When these are done and the oven empty and somewhat cooled, put in the bread. This rises very much in the oven if the first heat is kept low. However, thick-crusted, dry tasting bread is the result of too long baking, so govern yourself accordingly and do not bake bread longer than 40 minutes. When the bread is in you may be able to make room for a crock of beans or an escalloped dish of some cereal or vegetable that can be cooked now and reheated to good advantage later. Heat may be turned off entirely after the food is two-thirds done, if the oven is properly lined. Enough heat will be retained to complete the cooking.

If your oven is an asbestos lined one you may be able to do fireless cooking in it with the help of soap stones. It costs but a little time to find out and in summer the convenience is a most helpful one. Heat the oven until the indicator shows the "high heat" point has been reached. In the meantime have the food to be cooked well, heated through and bubbling briskly, as food in a fireless cooker does not get hotter than it is when put in. Heat the soap stones, which may be bricks for experimenting. Put these in the oven, then the food closely covered and close the oven. You can tell how well the heat is retained by watching the thermometer.

Some of the attachments for oil stoves that make these pleasant to use are the covered broiler with drip pan to catch the juices and the toasted and special griddle. There is also a hot water heater that is efficient and low priced.

Fashions Dept.

How to Order Patterns.

Order by number, giving age or measurement as required, and allowing at least ten days to receive pattern. Also state in which issue pattern appeared. If two numbers appear for the one suit, one for coat, the other for skirt, thirty cents must be sent. Address Fashion Department, "The Maritime Farmer, Sussex, N. B. Be sure to sign your name when ordering patterns. Many forget to do this.

Positively no patterns will be sold under 15 cents each, owing to advance in cost of same.

When ordering, please use this form:—

Send the following pattern to:

Name .....

Post Office.....

County .....

Province .....

Number of Pattern.....

Age (if child or misses' pattern).....

Measurement—Waist .....Bust.....

Date of issue in which pattern appeared. .....

CHILD'S DRESS.

By Anabel Worthington.

A girl begins to take notice of her frocks almost as soon as she passes the "rattle" age, but not until she has gone over the sixth year mark does she know how to take the necessary care of them to make mother's work easy. Therefore mother should select such dress models as will be no work to make, to launder or to slip on and off the girlie.

This illustration suggests the correct way to make a day dress for a girl of from two to six years of age. It shows the front with a yoke that is finished for lacing after slipping the frock on over the head. The upper edges of the dress fronts are neatly gathered and joined to the yoke, and a belt with its ends buttoned to the front sides is arranged over the back fulness. To match the sailor collar, the belt is of contrasting color goods; the cuffs on long sleeves have a piping to correspond. It rests with you whether the short sleeve is to be used instead.

For a play dress linen, gingham, cotton cheviot and like weaves are suitable, and for kindergarten wear plain ground woollen weaves and wool plaids and checks are excellent. There are no buttons or buttonholes to bother with and really one can cut out and finish several of these little dresses in a very short time.

The dress pattern No. 8114 cuts in sizes two, four and six years. To make in the medium size requires 1¾ yards of 36 inch material, ½ yard contrasting goods to trim 32 inches wide.

To obtain the pattern send 10 cents to the office of this publication.

GIRL'S DRESS.

By Anabel Worthington.

To help make school days the happiest in a girl's life Fashion is favoring the younger generation to a very marked degree when it comes to dresses. Look at the illustration and you will be convinced.

Of course, the collar of this dress is a big feature, for it is stylish and particularly becoming in its cut, but there are other attractions. The frock is made with a body lining and has the waist fulness gathered at the lower part, so that it blouses prettily over a two piece gathered skirt, making a belt unnecessary. The vest of contrasting goods—either silk, satin, piqué, crepe or broadcloth in opposing color—is finished at the top with a band of the dress material; the full length sleeves have a deep roll cuff of material in the vest, and the button decoration is a detail that is in excellent taste. When the girl turns her back we see a divided cape effect of the collar, so that the back view is as fascinating as the front.

Wool checks, plaids, serges, gabardines, &c., make charming little frocks for juniors, and any one of these will be suitable for the design. To distinguish it as a "best dress" velveteen, satin and other rich fabrics may be considered. If you will give this simple pattern a chance to prove its worth you will be pleased with the result.

The dress pattern, No. 8,121, cuts in sizes 6-14 years. To make in size 10 requires 2⅞ yards 36 inch material, ⅜ yards contrasting goods and ½ yard 36 inch lining.

To obtain the pattern send 10 cents to the office of this publication.

WHAT IS COLD PACK CANNING METHOD?

It was said in a previous article that the "cold pack" method was the one that the home housewife should follow, since it is the most successful for both fruits and vegetables and the easiest to follow.

" Cold pack" does not mean without heat; it means that the products are packed, cold, into sterilized glass jars. To the fruits, hot syrup is added; to the vegetables boiling water and a little salt. Then the sterilization is done in the partly sealed jars, making it impossible for spores to enter.

This does away with all standing over the open fire or handling hot foods, so that canning is not so unpleasant. For after the jars are once filled, then the work of sterilization can proceed almost automatically.

If vegetables are to be canned in this fashion the process of "blanching" should precede. This means that vegetables are first subjected to a quick bath of boiling water or live steam, then quickly plunged into cold water; then packed and the general directions followed.

Blanching has these advantages—it removes some of the excess flavor, especially with strong beans, cabbage, etc.; it reduces the bulk of the foods so treated; it whitens and makes firm many other foods and removes the skins most easily.

Another advantage of the "cold pack" method is that it has but one period of cooking—foods are packed cold into the jars, filled with hot liquid, then sterili ed at one time. This again saves labor and can lifting.

After the jars are filled with the food cut into convenient pieces or shapes, the boiling liquid must be added. If this is syrup, the thickness or "density" must be carefully noted. Certain fruits take syrup of one thickness, while others differ. The following table of syrup density will show what per cent. sugar solution results:

	Qts. water.	Syrup.
1 lb. 9 oz. sugar	3	25 per cent
1 lb. sugar.....	3	16 per cent
1 lb.....	1½	32 per cent
2 lbs. 3 ozs.....	3	35 per cent
2 lbs. 8 ozs.....	3	40 per cent

A common used syrup is three quarts of water and two quarts of sugar, boiled to a medium thin, medium thick or thick syrup.

This syrup is sugar and water boiled to dissolve sugar, but not sticky. Medium thick syrup is that which has thickened enough to roll or pile up over the edge of the spoon as it is poured out.

Medium thin is that which has begun to thicken and becomes sticky when cooled on the finger tip or spoon.

Thick syrup is that which is difficult to pour out of a spoon.

ARMS AND ELBOWS

A well known photographer recently told me that a really beautiful feminine arm is a rarity. And when I asked him whether the fine college and school athletic training most of our girls were getting did not benefit them, he said, "Yes, but a muscular arm is not necessarily a beautiful one."

Fortunately, however, the arm is easily beautified, more so than almost any other part of the body. But results will not be seen for a day or a week, or for several weeks. The beauty seeker must persevere.

First of all the skin is to be treated. The arms should be scrubbed in hot water with a little almond meal in the water, with soap and a flesh brush. This will make the skin red, but in time will produce a milky-white, clear, beautiful color. Then the whole arm is massaged with flesh-building cream or olive oil, and the more undeveloped parts are gently pinched with the fingers. The elbow—which unfortunately is rarely pretty—is massaged by placing the thumb of the opposite hand inside the bent elbow as a pivot, while the fingers massage in circular fashion about the outer part of the elbow.

Then, the arm is held out straight, the fingers spread apart. The hands are slowly drawn up into a fist, the fingers being as stiff as possible, so the tensing of the muscles can be felt along the lower arm. This is repeated several times. To develop the upper arm, the hands are made into fists and the arm is bent back upon itself, the

hands drawn towards the shoulders, the muscles being stiffened as much as possible.

NERVES

Nerves are the real or imaginary evil of almost every woman's life. It is doubtful which sort is worth to possess. The fancied kind can be cured by will power, but the real ones require a more devious method of cure.

There are two splendid things to do to overcome a nervous condition. One is eat, the other, sleep. Fat people are never nervous, big eaters are seldom nervous. When there is food in the stomach, the blood is drawn down from the brain, and, for a time at least, the nerves are quiet. And gradually sufficient good food will build up the system.

Sleep, of course, is another rebuilder. The nervous woman needs nine hours' sleep at least, either all at night, or at night and during the afternoon in the course of a nap. Then hours would be better yet.

However, neurotic women are apt to toss about and to sleep uneasily. The best way to overcome this—and this is good for the looks and should be practised by all but fat women—is to eat a few crackers and to drink a cup of hot chocolate or hot milk, just before getting into bed. This draws the blood from the brain, and induces an early and a dreamless sleep.

The nervous woman is never pretty. She is apt to have hollow cheeks, and the run down system shows itself by deep circles under the eyes, and fine lines that creep into the face. The eyes seem dull too. Besides, the nervouse woman being restless herself, has a restless effect upon her companions, so never gets credit for being fascinating.

SCOTCH HASH

One onion cut fine and cooked a little in beef dripping, then add cooked meat that has been put through meat chopper, and one-fourth as much fine crumbs of dried bread. Add salt and pepper and some gravy. If very little, add a little hot water after cooking a while. Cook slowly half an hour or more, turning carefully to brown it all. This is very rich and is better made of cooked roast beef, which is generally the poorest meat for hash. No vegetables in this hash.

SALMON LOAF

Take one can of salmon, freeing it from skin and bones and separating in fine flakes with a silver fork. Mix with two well-beaten eggs, one cupful of fine breadcrumbs, salt and pepper to season, one tablespoonful of lemon juice, one tablespoonful of melted butter, one tablespoonful of finely chopped parsley. Pack into a well-buttered mold, steam for one hour and put into the oven to brown.

To improve the flavor of an apple tart sprinkle the fruit with lemon juice after it is put into the dish and cover with tiny pieces of butter, then add sugar and nutmeg or cinnamon.

The Crisis!

Untold sacrifices are being made in defence of the world's liberty, assailed by the Hun, who declares he fights for "existence." Let us not forget that other crisis in which the fate of the dread Liquor Traffic, subdued just now by the necessities of war, is also fighting for existence.

Prohibition must be impregnably fortified ***now*** by means of proper enforcement in readiness for the struggle to come when Prohibition must be finally ratified or lost by the votes of the people in many provinces, including New Brunswick.

Alberta, Saskatchewan, Manitoba, Ontario, Nova Scotia and New Brunswick have adopted Prohibition during the war. Prince Edward Island has enjoyed its benefits since 1901. The great majority of districts in Quebec are "dry." That is the situation to-day, but remember, the crisis comes after the war.

SIR VICTOR HORSELEY AND HEREDITY

"That alcohol affects disastrously the minds and bodies of innocent, unborn children must be the undoubted conclusion of those who weigh the Evidence."

The total value of foodstuffs destroyed by the liquor traffic in 1916 was approximately $4,244,090.22. Add to this the immense waste of transportation facilities, clogged and hindered by carrying the grain to destruction, and again conveying the product of the breweries and distilleries to make precious men less efficient in this solemn hour!

Ontario's Splendid Record

Since September 16, 1916, Ontario has enjoyed good enforcement of Prohibition in all but a few districts. Not the most daring anti-prohibitionist hopes for a return of the curse of the traffic in Ontario. Here are some figures showing results in Ontario's largest cities for the last three months of 1915 and 1916:

ARRESTS FOR DRUNKENNESS

	Under License 1915	Under Prohibition 1916
Toronto	2,908	953
Ottawa	286	234
Hamilton	498	61
London	367	144
Brantford	152	16

Note.—"It will be noted that Ottawa has not much reduction in arrests for drunkenness. It is perhaps strange that it should show any reduction in the drunkenness record, inasmuch as it is separated only by the river from the license city of Hull."—PIONEER, Toronto.

Whether your district be under the new Provincial Prohibitory Law, or under the Canada Temperance Act, help us to arouse the full force of public opinion for vigilant enforcement of province-wide Prohibition.

Dominion Temperance Alliance

should be added in the rendering. Leaf lard makes the most desirable rendering, but if fat from the intestines is used it should be soaked in salted water for two or three days before rendering.

Always soak in cold water before washing all dishes in which milk, dough, egg and cereals have been cooked. Always soak in hot water all dishes that have had sugar or grease in them.

When rendering fat, throw in a handful of slippery elm bark, which can be purchased at any drug store, and the lard will keep sweet and fresh in the warmest summer weather. Any ordinary well covered crock will be all right to keep it in, and it can be canned hot. It will be advisable to keep it in as cool and dry place as you can find in your home. No salt

RICE MUFFINS

Two level cupfuls cold boiled rice, 2 leevl cupfuls flour, 2 level teaspoons of baking powder, 2 level tablespoonfuls sugar, 2 eggs separated, 2 cups of milkl level teaspoonful salt.

Mash rice. Sift flour, baking powder, sugar and salt together twice. Beat yolks of eggs, add whites beaten to stiff froth and stir into rice. Add milk and flour gradually and beat until smooth. Have the gem pans greased and a little flour sifted into each. Fill ¾ full of mixture and bake in hot oven 15 minutes. Serve as soon as taken from oven with butter or maple syrup.

CARAMEL CUSTARD

Three cupfuls of milk, 3 eggs, ¾ cupful of sugar, ½ teaspoonful of salt, 1 teaspoonful of vanilla.

Melt the sugar in a spider, stirring constantly until it becomes a light brown syrup. Scald milk and add melted sugar into it gradually and very carefully. When the mixture is smooth add it to the lightly beaten eggs; add salt and vanilla. Strain into a buttered mold, set in a pan of hot water, and bake in a slow oven until firm.

NO PERMANENT ROAD WITHOUT GOOD DRAINAGE AND SOUND FOUNDATION

(Continued from page 555)

subgrade, and the rolling and compacing of the subgrade before placing the foundation is therefore an economy. A compacted subgrade also enables the foundation of the road to better withstand the effects of heavy traffic, whereas a yielding subgrade tends to cause a sinkage of the foundation with consequent hollows and holes in the road.

Crushed stone where used as foundation for a macadam road should be not less than 6 inches in thickness when compacted, and the si_e of stone will usually be about that passing a 2½ inch ring.

Screened gravel of 1 inch to 3 inch size may be used in prace of crushed stone, and when placed in the road a filler containing some clay or loam should be spread in order to thoroughly consolidate the stones.

Such gravel does not interlock as crushed stone does and a thicker foundation course of gravel is therefore required.

Field stone used for a foundation may be laid in one course from 6 inches to 12 inches in depth and the inequalities between the stones filled with coarse gravel or crushed stone. The depth of the course should in all cases be suited to the average size of field stone available as it is not economical to break them to a definite size. A variation of an inch or so in the size of the stone is of no consequence since the surface stone will serve to even up all irregularities.

The Telford base may be composed of quarry stone which has been broken to size with a stone hammer. Such foundations have given good satisfaction when used, but the cost of hand placing the stones seems to have outweighed the advantages of this type of construction.

In conclusion it may be said that the adequate drainage of a road is the first requisite to permanence and if we add to proper drainage, a sound foundation, the cost of maintaining surface of road will be greatly lessened. Drainage and foundations are two very essential details of road construction and close attention to these points when designing and constructing a road will lead to better, more durable and more satisfactory roads.

VALUE OF MANURE FROM 24 STEERS

The manure from twenty-four steers averaging in weight close to 1,000 pounds each, and running loose in two box stalls at the Experimental Station, Kentville, N.S., covering a period of 120 days, or four months, weighed 112 tons, 640 pounds. The average for each day was 1,872 pounds or 78 pounds per steer. Straw bedding amounting to 10 pounds per steer per day was used, and all liquids as well as the solids were saved.

Chemists tell us that this fresh manure fro mfairly well fed steers contains in each ton 7¾ pounds nitrogen 3½ pounds of phosphoric acid, and 9 pounds of potash. When buying commercial fertilizer we pay 25 cents per pound for nitrogen, and 7 to 8 cents for phosphoric acid. Potash cannot be bought at any price, but in order to get at a fair valuation for the manure we should allow at least 5 cents per pound, the price of potash before the war.

A ton of the above manure at these prices would, therefore, have a value of $2.63.

At the valuation of $2.63 per ton, 112 tons 640 pounds would be worth $295.40, or $12.31 per steer, a little over $3 per steer per month. Considering that potash will each year become a greater factor in economical agricultural production, the value is even greater than that given above.

Nothing has been allowed in the above calculation for the value of the humus. It is estimated that the humus value of manures is 50 to 100 per cent. of the value of the chemical ingredients, depending upon the soil on which the manure is used and the manner of application.

It is a well known fact that half of the total value of the excrement from live stock is in the urine. If the liquid part is allowed to drain away through holes in the stable floor, or otherwise, over one-half of the value of the manure will be lost. Therefore, every effort should be made to conserve all the excrement voided by animals.

The water retained after twenty-four hours by 100 pounds of material used for obsorbents in the stable is estimated to be as follows:

Wheat straw, 220 pounds; oat straw, 285 pounds; well dried peat, 600 pounds; dry sawdust, 435 pounds; dried leaves, 162 pounds.—Experimental Farms Note.

HOW CHEESE IS BOUGHT

The following rules govern the purchase of cheese by the Imperial Cheese Commission, but are subject to alternation at any time:

1. Prices shall be fixed at which the Commission are prepared to purchase all cheese of different grades f.o.b. steamers Montreal or other ports available, at the option of the Commission.

2. There shall be three grades of cheese, known as No. 1, No. 2, and No. 3. Any cheese unsuitable for these grades will be classed as "Culls" and purchased according to their merits at the option of the Commission. No cheese will be accepted under ten days old.

3. Payment will be made in exchange for shipping documents accompanied with invoices, grader's and public weighmaster's certificates, all shipping charges being prepaid by dealers. Quantities of 500 boxes (5% more or less) to each bill of lading and invoice will constitute a delivery.

4. Payment will be made only after documents have been delivered in proper order to the satisfaction of the Commission.

5. White or colored cheese, or cheese of different grades, or cheese known as Quebec and Ontario makes, must be invoiced and shipped separately.

6. In event of delays in shipment taking place exceeding three weeks and three days from the date of grader's inspection, payments will be made thereafter under the following conditions:

Such cheese in all cases must be stored either in cold or ordinary storage, as required by the Commission, and approved warehouse receipts and fire insurance certificates must accompany invoices.

The dealer or dealers will ship such cheese at his or their own cost when instructed to do so by the Commission, giving a "bailee" receipt for his or their warehouse receipts. The "bailee" receipt will be returned to the dealers on delivery of shipping documents. In event of the Commission requiring dealers to store and carry cheese bbe yond the period of three weeks and three days, the Commission will pay the current cost of storage, interest and fire insurance.

All cheese to be coopered to the satisfaction of the Commission, and boxes clamped with iron hooping, as and when required, and shipped in good order. Cheese badly "boxed" will be graded lower.

8. Boxes are to be marked in such a manner as may be directed by the Commission, and each dealer will use a separate and distinct mark for each grade of cheese shipped by him, as may be directed by the Commission.

9. As graders can only examine samples of each delivery of cheese to the Commission, dealers shall be responsible for the weights and qualities of their respective shipments, notwithstanding inspection in Montreal, in the same manner as they would be if cheese were sold c.i.f. London rules.

10. Cheese to be free from any adulteration whatever, and all deliveries must be fresh current receipts.

Cheese held in factories or storage of any kind will not be considered a good delivery.

11. All invoices and documents must truly represent the grade of cheese tendered to the Commission, Any deviation therefrom on the part of any dealers will be deemed by the Commission sufficient reason for discontinuing to purchase further cheese from such dealers.

HOW TO EXTERMINATE RATS

Hearing a farmer remark that his entire flock of pure bred chicks were destroyed by rats last summer, it occurred to me that the ideas of one who has had some experience with rats might benefit others. I once lived on a farm on which they were in almost undisputed possession and in an effort to exterminate them I learned a good deal.

They increase rapidly, breeding three or four times a year and having about twelve in a litter. The young start t obreed at four or five months. It is estimated that they destroy ten times more than they eat, and considering heir ravages on young fowl and eggs it is well to do the utmost to keep the farm clear of them. If old straw stacks, piles of rubbish, etc., are cleared away and all safe retreats removed, a few cats (not house cats) will keep them down.

If all buildings have cement foundations 20 inches deep the foundations are rat proof, and if the space between the lath and sheathing is filled with concrete one foot high they will not enter the buildings except by the doors. For granaries, a concrete foundation and above this a half-inch mesh wire netting put round the building is very effective in keeping rats from gnawing holes in the wood round the sills to gain access. Rats will not gnaw the level surface of wood, therefore if the corners are protected with netting or sheet tin they will not enter the building so easily. No better harbor can be found than the old stone wall or foundation or the building built on wood sills with no excavated foundation.

Much ingenuity is called for in successful trapping. With wire box traps or cages it is a good scheme to put the trap inside an over-turned box, making a hole in the other box to lead right into the trap set aside. Cover the whole thing with some rubbish and put sausage or fried bacon in for bait. Leave unset for a few nights and it may contain twenty on the night it is set. If they get wise to the bait change it, or with steel traps cover with black tissue paper and do not bait at all. The ordinary figure four box trap will often prove effective when all others fail. I well remember trying for weeks to catch an old rat that seemed almost proof against traps. A barrel half full of water was set on his path. Covered with building paper fastened tight over the top. Bait was laid on it for a week. A cross was cut in the centre of the paper one evening and the whole family was swimming in the morning. We once left about twenty oat sheaves in the barn all summer. Towards fall there was no other feed round the buildings and we were surprised to find the pile moving with rat life. We went to the trouble to build a fence round this with sheet tin and netting. When the sheaves were lifed out the carnage was awful and the clean-up singularly complete. Poisons are not so satisfactory from the danger associated with their use. For rats in dwelling houses, barium carbonate is best as the rats leave the house for water and there die. This drug mixed with oatmeal and

FURNACE TIME ?

Well, it's admittedly the best and most convenient time to have a furnace installed. When you're considering the matter be good enough to remember that unsurpassed Wood Furnaces are MADE IN FREDERICTON by

THE SMITH FOUNDRY CO., LIMITED,
FREDERICTON, - - - N. B.

water, one pair poison to seven of oatmeal, or spread on fish, toast, cheese or bread and butter is worth trying. Strychnine crystals put in raw meat sausage or fat bacon is more effective than poisoned wheat. This bait is the best to use in poultry houses. It should be put in the centre of a small box and a larger box inserted over it. Holes large enough for a rat are made into each box and if fixed solid and well planned and baited are safe for chickens and effective with rats.

Another trap for poultry houses is a tin box sunk in the rat run. Two lids are made to fit loosely and hinged one-third distance from each end. A rat running out will tilt the lid and fall inside and the cover resumes its former position, enclosing the rat. If well set and partly covered it works very well. T. W. W.

CONTROL THE GRASSHOPPER

Grasshoppers did a lot of harm in New England last year. They begin to feed upon crops immediately upon hatching from the egg. Unlike many insects, there is no grublike larval stage, nor is there any resting or true pupal stage. They are active and able to hop about almost immediately upon emergence from the eggs. They are, however, unable to fly while young, as it takes from 70 to 90 days for them to develop wings. The farmer, should, therefore, attack the pest during its young stages, since not only less material and labor are required but they cannot fly to untreated fields as they often do when mature.

There are three principal methods of control: Destruction of the egg, trapping the insects in the field, and use of the poisoned baits. The eggs of grasshoppers are deposited in the ground, or in the crowns of plants. Where cultivating implements can be used, the ground containing eggs should be thoroughly plowed, or disked, and harrowed in the fall, as these operations prevent the eggs from hatching the following spring.

The most common method of trapping is by the use of a simple horse-propelled implement called a hopper-dozer. This consists of a long, shallow pan or trough, with a back and side wings rising at right angles to the pan, and is mounted on runners. The pan is constructed of galvanized sheet iron, the back and side wing may be built of wooden frame covered with stout muslin or light cotton duck, and the runners are made of wood or old wagon tires. The pan is kept partially filled with water, covered with a film of low-grade kerosene. As the hopper-dozer is drawn over the field the grasshoppers jump or fly against the back and most of them are precipitated into the oil-covered water in the pan. A slight touch of oil is fatal to the insects. These implements cannot be used on uneven, stony, or recently cleared land, nor in meadows or fields of grain where the crops have reached a considerable height. Even where they are used successfully, a good many grasshoppers escape being killed.

Poisoned Baits Best

The most effective method of control, according to a government bulletin, is the use of poisoned baits. Poisoned-bran bait has proved to be a simple, reliable and cheap method of destroying grasshoppers. This bait is prepared as follows: Wheat bran 25 pounds, parts green one pound, or white arsenate one pound, six finely chopped lemons or oranges, low-grade molasses, such as refuse from sugar factories, or cattle molasses, known as "black strap," two quarts, water three to four gallons. The bran and paris green or other arsenical are mixed thoroughly while dry, then the fruits are chopped finely and added, and lastly the diluted molasses is poured over the bait and the whole thoroughly kneaded.

A coarse-flaked bran is most desirable, although where this cannot be obtained easily, ordinary middlings or alfalfa meal may be substituted. A low-grade, strong-smelling syrup or molasses, however, is essential to the entire success of the undertaking. Crushed ripe tomatoes, watermelons, or limes may be substituted for the lemons or oranges, if necessary. Ordinary powdered white arsenic (arsenious acid) contains nearly twice as much arsenic as paris green and is comparatively low in price. The powdered form of arsenate of lead may be used; but in this case twice as much of it must be used as of the paris green.

The poisoned-bran bait mixtrue is distributed over the infested fields by sowing broadcast, either on foot or from a light wagon or buggy. A broadcast grain seeder, mounted on a wagon, has been used successfully for this purpose in the western portions of the country.

In applying the poisoned baits in orchards, care must be taken to avoid distributing it close to the trees, because severe injury o fruit trees occasionally results from such applications or arsenical poisons. In moist portions of the country, such as New England, the bait should be applied early in the morning to secrue the best results. Farmers should not be discouraged if the grasshoppers do not drop dead immediately upon eating the poison, as it usually takes 24 hours or more for the full effect of the bait to become apparent.—N. E. Homestead.

SWEET CLOVER A SAFE AND USEFUL PASTURE FOR STOCK

Sweet clover furnishes excellent pasture for horses, cows, sheep, and swine. Formerly, farmers have been much prejudiced against this plant because stock will not usually eat it when first allowed access to it. However, as a knowledge is gained of the advantages that sweet clover has for pasturing, a more favorable attiude replaces this prejudice, writes W. E. Bowers in Hoard's Dairyman.

tr-s esp?- y itrhoAia. i .t-o id dmfao

Sweet clover, if seeded in the early spring, will furnish grazing in early summer from four to six inches high, and may be grazed the whole season through if not pastured too heavily. It produces the first grazing in early spring of the second year, and it is at this time that stock may easily be taught to like it. There being no other green feed for them, and being anxious for such feed at this time, they will eat the clover very readily, and will gradually, but hastily acquire an appetite for it. After animals become accustomed to eating sweet clover, they ofen prefer it to all other common pasture plants, and usually will thrive on it equally as well as when on other pasture, if not better. However, sweet clover will gradually become woody, and every effort should be made to keep a sufficient number of animals on it to prevent this. If this cannot be done, it is well to keep the plants clipped back in order to stimulate the growth of new shoots. Ordinarily, from fifteen to twenty head of medium sized hogs are able to flourish on an acre of sweet clover, but better growth is obtained when grain is fed in connection with the clover. Sweet clover not only furnishes early grazing, but it grows for a longer period, and late pastruage is secured in the fall long after other pasture plants have ceased to grow. It admirably survives the mid-summer drouths, furnishing good succulent pasturage during the period when no other regular pasture plants are usually growing. It withstands tramping. Frequently, sweet clover is used to supplement other pasture.

In order to obtain best results from pssturing sweet clover, it is advisable to devote two fields to it, one being seeded the year after the other. By this method it is possible to transfer the stock from one field to the other in case the animals are grazing too heavily on one. Also, stock can be taken off the old field at the proper time in order to secure seed for future planting and still have the new field for pasturing. Furthermore, a good yield of nutritious hay can be obtained from the old field if hay it wanted instead of seed, provided the stock are not allowed to pasture too long before making the transfer which should be done about the middle of July.

Sweet clover rarely causes bloat. In this it has a great advantage for pasture over the common green forage crops. Bloating from alfalfa, red clover, and white clove roften causes serious loss, but sweet clover is ordinarily regarded as safe in this respect. This great advantage makes sweet clover especially preferred for pasturing cattle and sheep.

It is the belief of some that sweet clover taints milk and butter when fed to milk cows. However, this accusation is not proved, but on the other hand, according to statements of many growers, sweet clover neither taints milk or butter. An excellent flow of milk is produced from pasturing sweet clover.

The feeding value of sweet clover pasture is about the same as that of alfalfa and red clover. It is very palatable after stock acquires a taste for its bitterness. It does not produce the extreme washy effect which occurs with most other pasture plants.

In pasturing hogs on sweet clover, it is well that rings be put in their noses. They are very fond of the roots, and will destroy much of the crop by rooting. This is especially true of the first season's growth. It has been found that a better method to prevent this is to add some protein and ash supplement (such as meat meal) with corn. Enough animals should be kept on pasture to prevent the clover from becoming woody, and to encourage the growing of new shoots.

If desired, pasturing may be done the first season until the middle of August, and then a hay crop obtained when the sweet clover has reached its maximum growth in the fall. The second year's crop can be pastured until July 15, and then the sweet clover allowed to develop a seed crop.

The time that it takes to churn depends largely on the temperature of the cream at the beginning. If the cream is quite warn the butter will come very quickly; if it is too cold. the churning may have to be prolonged sometimes fo rhours before the butter granules will become large enough to free themselves from the buttermilk. Generally a warmer temperature in winter and a cooler in summer will be found best.

Because the cow gives a large quantity of milk does not necessarily follow that it is of poor quality, nor if she gives a small quantity that it is of good quality.

A low-producing dairy cow even of the most perfect type should never be depended upon to produce profitable offspring, for that unproductive taint in the blood will surely appear somewhere down the line.

Fir Shade Farm Dual-Purpose Shorthorns!

Several years ago I imported from Ontario three Dual-Purpose Shorthorn animals, and now have in my stable at Rothesay eight representatives of this breed. Two of the females are entered in the Record of Performance, and so far have done excellent work. If you feel disposed you might drop in and see these the first time you are in the vicinity. Perhaps some time when you are coming to the city you would let me know, when I could arrange to go to Rothesay with you.
P. R. L. FAIRWEATHER. St. John, N. B.

GOOD WATER SYSTEM ON ESSENTIAL PAST FARM EQUIPMENT

(Continued from page 559)

for the time being, rather than be reckless regarding a matter of so great importance. The principal of permanency, however, should always be kept in view, in making adjustments, and wherever reasonably possible durable structures should be erected rather than temporary affairs.

No one plan can be suggested that will suit all locations and conditions but with the exercise of good judgment and industry no farmer that can make the farm pay at all should long be without a good water system of some sort.

ALFALFA TIPS

(Continued from page 556)

There will be no hay the first year. The second year the alfalfa will be ready for cutting and two crops will be available for the growing season. To get the best quality of hay the cutting must be done when the plants start to blossom, which will be the latter part of June the first time and early in August for the second time. The crop should not be cut late in the season. Alfalfa should not remain exposed in the swarth for any length of time.

The first year the field should be clipped with a mower when the alfalfa and weeds are about six inches high, and the clippings may remain on the field to form a mulch. This will hold the weeds in check. For the alfalfa it is best to have the cutting bar of the mower set so that it will not injure the crown of the plant. It is advisable to clip two or three times during the summer. The last clipping should not be later than August 15, because considerable growth should remain on the field as a winter protection.

It is highly desirable to keep stock from grazing on alfalfa the first year. In fact, alfalfa should not be pastured excessively at any time, and no grazing should be contemplated until the crop is thoroughly established and the plant roots developed. The field should be at its best the third or fourth year after seeding. Pasturing close the first year will have a tendency to injure the alfalfa crowns, and where the stock are allowed to run at will the surface of the field may be roughened by tramping when the soil is wet.

The practicibility of the various ways of getting alfalfa hay into condition for the mow or stack will depend largely upon the locality, local weather conditions and the ultimate value and use of the hay. Just which method should be used is largely a matter of the farmer's individual judgment.

TO RESTORE VIGOR AND STRENGTH TO A FEEBLE PLANT

(Continued from page 560.

Obtain from a garden or field some fertile loam, which has been enriched with animal fertilizers. A dense clay is not so suitable for the purpose as a lighter soil.

Add a tablespoonful of pure bone flour to each quarte of loam, mix thoroughly and let the mixturo stand several days.

Turn the plant top downward, holding it with one hand close to the roots, and strike the edge of the top of the pot on box or table gently until the plant with the entire mass of soil on its roots comes out. Lay the plant down, brush the pot and wash it in boiling water to kill all germs, and then immerse it in clean water till it absorbs all the water it can.

With a skewer or wire nail go all round and above and below the mass of soil on the plant roots, and scratch away an inch, more or less, injuring the roots as little as possible.

Now place in the bottom of the pot some broken pieces of plant pot or charcoal or oyster shell, so that the soil may not clog the hole in the pot and prevent drainage, and above this put an inch of good loam. Place the plant in the centre of the pot. Fill in the space between the mass of soil left on the plant roots and the sides of the pot with loam, making this so firm with the end of a stick that the new loam and old soil on the roots form one mass; fill in above the old soil with loam nearly to the top of the pot.

Submerge the potted plant to the top of the pot in a pail of water for five of ten minutes, then set it where it will have the temperature and light which it requires, shading it for a few days, if it seems to require it, with a single thickness of newspaper laid above it during the day, and keeping the soil moist, but not wet.

When the plant begins to grow, but not till then, stimulate it with liquid fertilizer made of cow of sheep manure and water. Use the pure liquid, not the sediment. Use it the first week the color of rather weak tea, and increase gradually till it is the color of strong coffee.

Apply the fertilizer once a week, in the morning of a sunny day, when the soil in the pot is already moist.

This treatment is good for any plant, especially an old one that has begun to show signs of deteriorating. When it becomes necessary to repot the revived and growing plant again a pot one size larger than the old pot may be used, and the plant repotted in a compost of one part well-rotted cow manure to four parts loam or rotted sod, or one part sheep manure to eight parts loam, to which is added one quart of pure bone meal or flour to each bushel of compst. This compost should be thoroughly mixed at least a week, preferably longer, before it is used.

The treatment outlined is based upon a few facts: A sick plant cannot withstand insect attacks, or the shock of having its roots entirely bared, or a potting compost containing a large percentage of manure that in its feeble state it cannot use. It does require the most favorable conditions as regards temperature, light and moisture.

It is easier to keep weeds from starting than to kill them when once well developed. Harrowing once or twice before planting time kills many weeds and saves much labor later. Weeds take nourishment and pump moisture from the soil, and thus rob the plant.

Volume 22. SUSSEX, NEW BRUNSWICK, JULY 24, 1917. Number 20.

Progressive Agricultural Legislation in New Brunswick--Enacted at the 1917 Session

The Sheep Protection Act

An Act in Addition to and Amendment of an Act Respecting Protection of Sheep from Dogs, being Chapter 97 of the Consolidated Statutes, 1903.

Passed 22nd June, 1917.

Be it enacted by the Lieutenant-Governor and Legislative Assembly, as follows:

1. The following is added as subsection (1) of section 2 of Chapter 97 of the Consolidated Statutes 1903.

(1) Upon the production of a certificate from a qualified veterinary surgeon that a bitch has been spayed, the amount of tax shall be one dollar.

2. Section 3, sub-sections (1) and (2) of the said Chapter, is hereby repealed, and the following is enacted in lieu thereof:

3. On the presentation of a petition of ratepayers, being householders, to the number of twenty-five, in any municipality, to the Municipal Council, the said Municipal Council shall, by by-law provide that this Chapter shall apply to such municipality from and after the passing of such by-law, and shall be in full force and effect in such municipality.

3. Section 4 of the said Chapter is hereby repealed and the following is enacted in lieu thereof:

4. The assessors of every parish of a county within which the by-law has been duly passed, as provided in the preceding section, shall, at the time of making their annual assessment, enter on the assessment roll, in column prepared for the purpose (Form A), opposite the name of every person assessed, and also opposite the name of every resident inhabitant not otherwise assessed, being the owner, possessor or harborer of any dog or dogs, the number and sex of such dog or dogs by him or her owner or harborer, and the assessors of any parish of a county within which the said by-law has been duly passed shall, in the manner in this section provided, set down the number of bitches and the number of male dogs owned or harbored by each person.

4. Section 5 of the said Chapter is hereby repealed and the following is enacted in lieu thereof:

5. The owner, possessor or harborer of any dog shall, when required by the assessors, deliver to them, in writing, a statement showing the number and sex of the dogs owned or harbored by him, and for every neglect or refusal to do so, and for every false statement made in respect thereof, shall incur a pnalty of five dollars, to be recovered with costs before any Justice of the Peace.

5. Section 8 s,ub-section (1) and (2) of the said Chapter is hereby repealed and the following is enacted in lieu thereof:

8. (1) The money collected under this Chapter in any municipality outside the limits of a city or incorporated town shall constitute a fund for the purpose of satisfying such damages as arise from dogs killing or injuring sheep or lambs in such municipality outside the limits of such city or incorporated town, and the council of such municipality may, when called upon as hereinafter provided, disburse and pay out of such fund, for the purpose of satisfying damages arising as aforesaid, to the extent of such fund; provided, however, no damages shall be paid until the end of the then current year, and should the fund not be sufficient, damages shall be paid pro rate.

(2) The council of any city or incorporated town in any county, the municipal council of which shall have passed the by-law authorized by section 3, shall, on the first day of January, in each year, pay over to the treasurer of such county fifteen per centum of the whole tax collected under the provisions of this Chapter within such city or incorporated town during the year then last past, and the fifteen per centum when so paid shall form part of the said fund in this section above mentioned, and be applied in the same manner and to the like purposes as the portion of such fund assessed and collected in the county outside of such city or town.

6. Sub-section (1) of Section 15 of the said Chapter is hereby repealed and the following is enacted in lieu thereof:

15. (1) The owner of any sheep or lamb killed or injured by any dog shall, where the council of the municipality shall not have passed the by-law authorized by section 3, be entitled to recover the damage occasioned thereby from the owner or keeper of such dog, by an action for damages or by summary proceedings before a justice of the Peace, or information and complaint before such Justice, who is hereby authorized to hear and determine such complaint and proceed thereon in the manner provided by the said Chapter 123 and any Acts in amendment thereof, in respect to proceedings hterein mentioned, and such aggrieved party shall be entitled so to recover in such action or proceedings, whether the owner or keeper of such dog knew or did not know that it was vicious or accustomed to worry sheep.

7. Section 18 of the said Chapter is hereby repealed and the following is enacted in lieu thereof:

18. The owner of any sheep or lamb killed or injured by any dog in any municipality in which a by-law under section 3 is in force may, within thirty days, apply to the council of the municipality in which such sheep or lamb was so injured, or any committee thereof appointed for such purpose, for compensation for the injury, and if the council or committee (any number of which shall be competent to administer an oath or oaths) on examining the parties in the premises, is satisfied that the aggrieved party has suffered damage, they sholl awrad to the aggrieved party for compensation a sum not exceeding two-thirds of the amount of the damage sustained by him.

8. Section 19 of the said Chapter is hereby repealed and the following is enacted in lieu thereof:

19. After the owner of any sheep or lamb has received from the municipality damage for the loss of or injury to any such sheep or lamb, under the preceding section, his claim shall thenceforth belong to such municipality, and it may enforce the same against the offending party by any means or form of proceeding that the aggrieved party might have been entitled to take for that purpose, in the name of the aggrieved party or in the name of the County Treasurer of such municipality.

9. Chapter 20 of 7 Edward VII, is hereby repealed.

A War-Time Measure

An Act to enable the Cities, Towns and Municipalities of the Province to borrow money for the purpose of purchasing food and other necessaries for the purpose of assisting the inhabitants of any such city, town or other municipality in supplying themselves with such articles during the continuance of the war now being carried on between Great Britain and her Allies, and the German Empire and its Allies.

Passed 22nd June, 1917.

WHEREAS, the cost of living has rapidly advanced and is still advancing and is likely to entail upon certain people of the Province great hardships.

AND WHEREAS, it is deemed advisable to enable the various cities, towns and other municipalities in the Province to borrow money to purchase food, fuel and other necessaries and re-sell the same to the inhabitants of such cities, towns and other municipalities without profit.

Be it therefore enacted by the Lieutenant-Governor and Legislative Assembly as follows,—

1. It shall be lawful for any city, town or other municipality in the Province to borrow money and issue debentures therefor to an amount not exceeding twenty-five thousand dollars to be used and applied for the purpose of purchasing to the best possible advantage, and at the lowest cost at which the same may be obtainable, such food, fuel and other necessaries; provided however, that the City of Saint John is hereby authorized to issue debentures in accordance with the provisions of this Act to an amount not exceeding fifty thousand dollars.

2. The City, Town or Municipal Council of any city, town or other municipality may by resolution at any meeting thereof declare its intention to take advantage of the Provisions of this Act, and at such or any subsequent meeting or meetings from time to time, fix the amount that the city, town or other municipality may borrow hereunder, and make all necessary rules and regulations and appoint all persons necessary for carrying the same into effect.

3. Any debentures issued under this Act shall be issued in the manner and form prescribed by Chapter 6 1 George V, (1911) and shall bear interest at a rate not exceeding five per centum per annum payable semi-annually to the holder of the coupon at the office of the City or Town Clerk or at the office of the Secretary-Treasurer of any Municipality, as the case may be, and said debentures shall be redeemable at such time or times and at such place as the city, town or other municipality issuing the same may be resolution of its Council provide.

4. All moneys realized from the sale of any debentures under this Act, shall be deposited in the name of the city, town or other municipality borrowing the same in some chartered Bank in such city, town or other municipality and in case there be no Chartered Bank in such city, town or other municipality, then in a chartered Bank most convenient to such city, town or municipality, therein to be kept at interest until required for the purchasing food and other necessaries authorized by this Act, for tho payment of the interest coupons on the debentures issued hereunder, and for the payment of any charges and expenses arising out of the carrying into effect the purposes of this Act; and all moneys received from any sales of food or other necessaries shall be deposited in a like manner, and shall remain so on deposit until required for the purposes of this Act, and on this Act ceasing to operate as hereinafter in the next succeeding section provided during the continuonce of the same, and all moneys so on deposit or in the possession of any such city, town or other municipality, and all money due and owing any such

city, town or other municipality for food or necessaries sold under this Act, when collected, as well as moneys received under sales made under the next succeeding section, shall be used and applied by each city, town or municipality in the redemption of any debentures and interest thereon issued under this Act.

5. This Act shall continue in force and operation until peace is declared in the said war, unless the operation shall be extended by Order-in-Council published in the "Royal Gazette" for a further period to all or any of the cities, towns or other municipalities who may have issued debentures under the provisions thereof. Provided, however, that any municipality may, after the operation of the Act has ceased, dispose of any food or necessaries then on hand and conclude and wind up any business or transaction connected with the sale or purchase of all food or necessaries under the provisions of this Act.

6. This Act may be cited as "The Act relating to the high cost of living."

An Act to Facilitate the Drainage of Farm Lands.

Passed 22nd June, 1917.

Be it enacted by the Lieutenant-Governor and Legislative Assembly, as follows:—

1. Whenever it shall be necessary, for the proper drainage of any farm land, that a ditch or drain should be run through the property of any adjacent owner or owners, the owner of the land requiring or to be benefitted by such drainage may apply to the Municipal Council of the County within which such land or within which the larger part thereof, is situate, for permission to construct such ditch or drain.

2. The said Municipal Council shall thereupon appoint a competent civil engineer or land surveyor to investigate the need for such drainage and estimate the cost of the same, the damage which will be done to the lands through which such ditch or drain may be run, the value of such drainage to the land to be served by such ditch or drain, and the amount which, in his judgment, should be assessed upon each property which will receive benefit from such drainage. Such engineer or surveyor shall, before making such report, notify each owner of land to be affected by such drainage, of the proposed ditch or drain, and shall endeavor, so far as possible, to have the same the parties interested. In case he should fail to obtain such agreement, the Council upon consideration of such report, may make such order as it shall deem expedient, which shall be binding upon all parties interested.

3. If the applicants for drainage shall deposit with the County Treasurer an amount of money sufficient to cover all damages to be caused to adjacent lands by the construction of the ditch or drain for which he applied, as estimated by the said enyineer or surveyor, toyether with the expense of investigating and the said report, the Council may grant him permission to construct such ditch or drain, and shall pay out the sum so deposited to the persons entitled thereto according to the said report.

4. In case any of the persons entitled to land through which any such ditch or drain is proposed to be constructed shall be an infant, lunatic or non-resident of the Province, any judge of the Supreme or County Court may, on the application of the person desiring the construction of such ditch or drain, make such order for the service of such person or the protection of his interests as he may judge to be fair and reasonable.

TALK ON FEEDS; THEIR FUNCTIONS IN ANIMAL LIFE

Millions of tons of feeds are fed to domestic animals every year and the value of these feeds run into billions of dollars. In taking up a discussion of feeding we should first consider the use to which these feeds are put by the animals.

First and formost feed is utilized by the animal to maintain its life. Several operations are going on at all times in the animal body requiring energy that must be supplied in the form of feed. These are:

(1) Respiration or the act of breathing, caused by the alternative contraction and expansion of the diaphragm and chest walls.

(2) Circulation, caused by the pumping action of the heart.

(3) Digestion, caused by the secretion of digestive fluids and the spasmodic contraction of the intestines to move their contents along. Chewing and swallowing the food requires energy and are the start of the digestive process.

(4) The natural body movements of the animal and the repair of tissue broken down in these activities.

Second, food is sometimes required to keep the animal warm. In ordinary weather sufficient heat is produced by the body activities mentioned above to keep the animal warm, but in severe weather or when the animal is unduly exposd, additional heat must be supplied by the oxidation of foods. This might very properly be listed under the first point, as it is necessary to the maintenance of life, but when animals are properly cared for, little food is used in this way and hence it may be listed separately.

Third, growth in young animals requires a great amount of feed particularly adapted to the needs of the growing animal.

Fourth, the development and nourishment of the young, before and after birth requires feed that must be supplied to the mother and transformed by her so that it can be utilized by the young.

Fifth, production of any kind requires feed. In draft animals feed must be supplied to be transformed into energy by the animal body. In milk production feed is taken into the body and transformed into a product available for human use. This is, of course, closely associated with the maternal function, mentioned in point four, but the fact that cows are bred with milk production very highly developed makes this factor in the use of food other than nourishing the offspring. In sheep, feed must be given for the proper development of wool.

Sixth, the production of fat requires food as every feeder knows in these days of high-priced feeds. While the laying on of fat is of primary importance in meat animals, it may be considered last, as this function is taken care of in the animal body after all of the other factors mentioned above are fully covered. It is only nature's way of storing energy against a day of need. The animal body stores food in excess of immediate requirements in the form of fat that may be drawn on later.

Every one, of course, understands that food is needed sufficient to cover these factors in the animal's requirements, and it will be seen that these points are closely related. However, when we consider actual practice, we wonder if all owners of brood sows, for instance, understand the additional food requirements to produce normal litters of pigs. The brood sow may be kicked about the farm to pick up her living as best she can from the time of weaning one litter until the next is due. Again, the cows milked on some farms are expected to return a good supply of milk from a very limited ration. The hat-rack horse is but another example of an animal given insufficient feed to care for vital bodily needs and the work he is expected to do. He is treated too much like Pat's horse that he tried to break of the expensive habit of eating, just when he became accustomed to go without food, he "up and died."

C. H. CLINK.

QUACK GRASS IS BECOMING A GREAT NUISANCE

Quack grass is one of the very worst weeds with which the farmer has to deal. There are comparatively few farms anywhere in Ontario or Quebec where it is not known as a desperately hard plant to keep under control. As one travels over lines of railways or other means of transportation this weed is seen on almost every hand; in meadows, in grain fields, on pasture lands, by the road sides, in wood lots, slashings, lanes, yards and lawns, in short everywhere. While there are no statistics showing the actual loss to the country and the farmers by the ravages of this weed, yet it is apparent to the most casual observer that it must be very great. Where this plant gets possession of the land it almost completely crowds out any cereal crop and greatly lessens any other that is cultivated where it is allowed to remain.

The reason for its common appearance, no doubt, is the fact that it is so difficult of eradication. In addition to this fact, however, it is a most insinuating weed and one is not likely to know anything about its intrusion until it has gotten a strong foohold and bids defiance to all who are opposed to its complete mastery of the soil where it locates.

Notwithstanding the determination of this usurper to maintain its hold upon the land, however, where it has taken possession, it is yet not beyond the reach of a careful and persistent farmer, who by one means or another can overcome and drive it off his premises.

This plant belongs to that class of weeds called by some "seeding and sprouting perennials." This is by far the most difficult class of plants to eradicate. The jointed runners will not only send up new plants while they are attached to the parent stalk, but if cut or broken and carried about, the pieces will grow, forming new centres of distribution. These runners have great vitality. They may often become dried and lie dormant for a long time; then, like a seed, when the proper conditions are presented, spring into life. Thus it will be readily understood how ordinary cultivation is a means of spreading rather than destroying such plants.

The general treatment for this class of pest is to put the land into some hoed crop, where practicable and by constant cutting off at the surface of the ground, smother it out by not allowing sufficient leaf growth to gather the necessary food from the air.

Summer fallowing will accomplish the same result if thoroughly and properly done, not a llowing the plants to make an appreciable growth at any time and using certain tools that will shave the whole surface cutting off everything. When the weather is dry and hot the ground may be plowed as soon as the crop is off, with the same result, by keeping all growth under until vegetation ceases and then fallow with shallow plowing. This followed by a corn crop the next season should clean a field of quack thoroughly if the work is well done.

One of the best methods is to plow shallow late in the fall and again in the spring, but deep, in preparation for a corn or other hoed crop. The writer cleaned very thoroughly a piece of land this way, while others again claim that the spring plowing should be shallow. In conversation recently with a gentleman connected with a Government farm, he stated that he knew of a case where great benefit had been derived by plowing the land the ordinary depth twice in the one season; once in the summer and again in the autumn with cultivation between the intervals.

From the experience of diffrent nn it may be gathered that any two plowings either shallow or deep in the second operation, where all growth is kept down in the mean time, is particularly destructive to this persistent plant.

While the whole weed problem is a serious one and the revenue of the country is greatly reduced by the presence of these intruders it is safe to affirm that no energetic man need fear to go on the land for fear of being over-run by these pests; for by the adoption of a proper rotation and a careful consideration of the peculiarities of growth together with common sense methods of cultivation the most persistent weeds can be kept under control without great expense or serious interference with the regular farm practice.

PLUGGING THE LEAKS PUTS DAIRY FARMING ON PROFITABLE BASIS

I have always been an advocate of a system of farm accounting that would leave no doubt as to whether I was making an actual net profit on investment. It was evident that any manufacturer would pursue such a course, and his remaining in the business would depend on the result. Holding as I do that any farmer who keeps live stock is a manufacturer of milk and meat products, I was convinced that he should follow somewhat the same system as his brother who turns out grain-binders or sewing machines.

Accordingly, I decided on an analytical accounting of my stock-in-trade. Due allowance was made for the initial cost of calves, etc., of housing, labor, interest insurance, and a score of miscellaneous expenses. The complete list was quite a formidable one, and proved most illuminating. It showed me that a herd of first-class dairy cows had really to go some if they paid the bills and broke even. As for the steer and the hog, it showed me that from birth to block no combination of food stuffs could be fed to them without saying good-bye to a fair margin of profit that these same grains might have brought if sold directly for cash. What was the use of all this extra burden and responsibility? Why not, I thought, simplify matters by selling the crops for cash, and take it easy?

I used to get some satisfaction when addressing farmers' institute meetings in dragging out my "financial problem" by way of a caution to some "back to the land" enthusiast, who thought he was going to get rich at the ancient and honorable occupation of farming. On one such occasion, a farmer in the audience offered this suggestion as a possible remedy: "Do you," he said, "credit your animals with everything that is due them? There may be a hidden profit." At the time I was not particularly impressed, but every now and then the idea came wandering back to me and persisted in getting some consideration. After turning the matter over in my mind, I finally reached the definite conclusion that there was not only one hidden profit, but several. We had been crediting the stock with only the direct profits while there were a number of indirect ones that certainly merited attention. For instance, there was the manure. Of course, it had not been forgotten altogether. We had lightly jotted it down at $1.00 a ton, and let it go at that. But the chemist said that it conained fertilizing elements that had an average commercial value of at least, $3.00 a ton. Even then they took no account of the humus content and its beneficial effect on the physical condition of the soil. Its

real virtue can better be realized when, after several years there is observed a decided increase in crop production. Such development means an added income which should be credited to the live stock on the farm.

Solution for Fertility Problem

Then, live stock conserves fertility by affording a home market for those crops best adapted to soil improvement. Grain growing as the sole revenue producer will impoverish the land as many farmers of the old school discovered to their cost. Live stock encourages the growing of clover—a fetrilizer in itself; corn and roots which mean an economical cleaning of the land by inter-cultivation at regular periods; and cereals to furnish straw and to seed down with, while growing a crop. Thus it will be seen that stock farming demands a type of crop rotation that is best for the land, for the animals kept, and for the farmer himself in the labor-saving methods of marketing all the crops. Hence, another hidden profit should be checked up in favor of the stock.

Again, did you ever notice how each class of stock fits into its own peculiar niche in utilizing the various waste products about the farm? If the corn fails to ripen there is no market for it, but the hog will turn the ears into ten-dollar pork. Stacks of straw that the western grain farmer burns become an asset on a stock farm by being turned into feed and bedding, thus getting back into the soil to replace the plant food it had previously extracted. A flock of sheep will turn a weedy farm into a clean one, thereby enhancing its cash value. Poultry converts grass, scattered grains and insects into meat and eggs, while the hogs and calves made their greatest gains on skim-milk, buttermilk or whey—the by-products of the dairy.

The Factor of Stability

The efficiency expert of modern business finds his chief usefulness in plugging the leaks. It is just there that the live stock farmer secures another of his hidden profits. Live stock fed on the farm for production of milk, butter, cheese, meat, eggs, etc., has stability as a business proposition that makes it most desirable. The growing of grain crops as a money-making occupation means a pretty constant gamble with the weather conditions and markets. Then, too, the mining of the soil must sooner or later lead to its depletion. It is simply a case of robbing Peter to pay Paul and is frequently the first step to the poorhouse. On the other hand, by having the crops swing around the live stock as a central pivot, it will be found that those which best feed the stock are also the soil builders. It is like putting the money in the bank and drawing interest on it for the proverbial rainy day. This existence of a proper balance giving stability to the business, is a hidden profit that must in all fairness be attributed to the live stock.

I believe that there are few who have experience in handling live stock but will admit that the work is broadening in its effect upon the farmer itself. The interest it creates demands study which in turn is educative. There are problems in plenty to be worked out, the solution of which stand for greater progress, a larger bank balance, and by no means least, a deeper love for one's vacation. Should not such a result be tabulat-McKenney in O. V. J.

TO PROPERLY CAN STRAWBERRY FRUIT

Of all the products easy to can, strawberries are perhaps the hardest. Although keeping perfectly, they are so frequently tasteless and unattractive that many housekeepers do not attempt to can them. Properly canned, however, they make a beautiful product. Freshly picked, sound berries should be washed, hulled and packed carefully in the jars. Strawberries need a good syrup to secure the best flavor; one and half quarts of sugar to one quart of water boiled to medium thick is about right. This should be added until the jars are full, rubbers and tops should be put lightly in position, and the jars sterilized in a hot-water canner for eight minutes, after which they should be removed and the tops tightened.

Best results are secured when strawberries are sterilized at a temperature of not more than 212 degrees—boiling temperature. Sixteen ounces of berries and seven ounces of syrup will about fill a pint can. Some housekeepers secure good results by pouring hot syrup over the berries and allowing them to stand a few minutes in a covered dish before packing in the jars. This gives a fuller pack and removes much of the objectionable shrinkage in the fruit. Strawberries should not be canned in tin unless the cans are lacquered.

Strawberry sun preserves are made by using equal weights of strawberries and sugar, boiling slowly in a preserving kettle for ten minutes, skimming frequently, and then placing in glass-covered platters in the sun for three or four days. The berries may then be packed in wide mouthed bottles and sealed with paraffin, if fruit jars are not available.

An exceptionally fine product may be made as follows: For each two boxes of berries make a syrup of two pounds of sugar and half a pint of water. Let the syrup boil until it reaches a temperature of 265 degrees. Add the berries and allow to boil very slowly in an uncovered kettle until the temperature has again mounted to 220 degrees. Remove from the fire, cover and allow to stand overnight. In the morning fill the jars or bottles with the berry meat, place in a canner filled with cold water, and bring to a boil. Remove the jars or bottles, seal the jars, or cork the bottles, and dip them in paraffin. The result will be a solid pack of whole preserved strawberry meat.

A delicious strawberry jelly may be made of the remaining fruit juice by adding sufficient sour apple juice so that a spoonful of juice combined with a spoonful of alcohol will form a gelatinous substance. Apple pectin may be used if it is available. Boil the juice until two drops will form on the edge of a spoon held sidewise, and pour at once into sterilized jelly glasses, tumblers or other containers. Cover with paraffin. Rapid cooling is essential for good color in jelly.

Sixteen boxes of berries and eleven pounds of sugar will make about eight pints of whole strawberry preserves and fourteen glasses of jelly.

Strawberry jelly cannot usually be made without the addition of some other fruit juice, although early berries may sometimes be made into a fair jelly by reducing the amount of sugar and boiling the product somewhat beyond the usual jelly-making stage.

A scant teaspoonful of tartaric acid to half a pint of juice will aid. Equal amounts of orange pectin juice and strawberry juice make a very good jelly. Two parts of kumquat juice to one part of strawberry juice make an out-of-the-ordinary jelly. Currants and strawberries may also be combined to advantage in jelly making.

Kinds of Syrup

1. Thin syrup is sugar and water boiled sufficiently to dissolve all sugar, but is not sticky.

2. Medium-thin syrup is that which has begun to thicken and becomes sticky when cooled on the finger tip or spoon.

3. Medium-thick syrup is that which has thickened enough to roll or pile up over the edge of a spoon when you try to pour it out.

4. Thick syrup is that which has become so thick that it is difficult to pour.

THE MAINTENANCE OF ORGANIC MATTER IN FARM SOILS

It is a recognized fact that as a rule a soil is productive in proportion to the amount of humus or vegetable matter which it contains. It is of the utmost importance therefore that all lands kept for the purpose of crop production should be liberally supplied with this necessary material.

The original source of humus or organic matter came from the leaves of trees and decay of plants that will grow upon the least possible supply of this element in the soil and by slow accumulations during the centuries has gradually increased the fertility of most lands until to-day they have enough humus to grow profitable crops. However, where this is lacking an effort should be made at once to supply the deficiency, which can be accomplished by the adoption of a judicious system of farming.

Lands continuously cultivated gradually diminish in productive capacity. The growth of any kind of vegetation takes up a certain amount of various mineral elements from the soil. The discovery of this fact and the additional one that these several substances are necessary elements of plant food, naturally led to the conclusion that the loss in productive capacity must be due to the diminished supply of mineral plant food, and that any successful effort to maintain or increase the fertility of a soil must lie in the direction of replacing these elements by artificial means.

It is the gravest error, however, to consider that the fertility of a soil depends upon its supply of mineral plant food; neither is it any more correct to consider the supply of soluble mineral plant food in any soil as a definite amount, like so much horse feed in a barrel, to be drawn upon until exhausted, with no power in the barrel to renew the supply. All soils have their origin in the rock masses of the earth and what has been developed from a given material may continue to be developed therefrom under like conditions; under improved conditions the rate of its development may be accelerated. If there were no means of replacing these elements from the foundation soil the estimates that have so commonly been made as to the number of years a given soil might be expected to produce a certain crop, based upon the amount of plant food in the soil as shown by chemical analysis, and the quantity taken up by an average growth of this crop, would be entirely erroneous.

This method of calculation takes no account of leaching, which in humid or semi-humid climates is very great, there being leached out of an average soil by the percolating waters from five to seven pounds of plant food for every pound taken up by the crop.

It is also a decided error to refer to the sale of so many pounds of plant food contained in grain, as the only or even the greatest evil resulting from the continued production of grain crops and their sale from the land. Even if the whole crop were returned to the soil, there would be replaced only 15 to 20 per cent. of the mineral plant food that has been given up by the soil during the production of that crop.

As the rock fragments are decomposed and dissolved a part is taken up by the plants, and, as we see, a much larger part is carried away by the percolating waters to the sea, to be again laid down, to go through the process of rock formation and perhaps at some future day to repeat the process now going on.

It may still be asked, what causes the reduction in fertility, if not the reduction of soluble plant food?

The answer is, a lessening of that element in the soil which not only affects, but very largely controls all the factors of fertility heretofore discussed, namely humus.

Since the maintenance of humus is such an important matter, let us look for a little at the sources from which the supply comes, and from which it must be maintained. Originally, as we have seen, the supply was from a few primitive weeds, and the leaves of trees decaying on the ground. Since the latter, at least, is no longer available we must look to other sources of supply. These are chiefly from three sources, namely, farmyard manures, the pasturing of stock on land, and the growing and plowing down of leguminous crops.

It is estimated that about forty per cent. of the organic matter that is fed to animals is returned in the manure. This, of course, includes all the bedding which should, at least, be sufficient to absorb the liquids of the manure pile. Heiden found that 47 per cent. of the dry matter fed to a horse was recovered. A full grown steer returned 56 per cent. of the dry matter of the feed.

R. E. Denel fed 46 cows for one week and weighed and analyzed feed, bedding and manure. The cows had been on the same ration for some time previous to the test. He found 45 per cent. of the dry matter and 43 per cent. of the organic matter of the feed eaten was recovered in the manure.

Young animals, lean animals, or, those that are producing milk or work, digest their food closely. From the limited information available, it appears as if one might count on a return of about one-half of the organic matter of the food, but with usual methods of handling probably not over one-fourth to one-third reaches the field.

The practise of pasturing down crops is a method of saving labor as well as increasing and maintaining the supply of humus and in a general way of adding fertility to the soil. This method is particularly useful with hogs and sheep where food is given them in addition to that obtained on the field, causing an additional supply of plant food and resulting in the filling of the soil with a dense mass of roots and close sod which, when decayed leaves a great amount of humus in the land. The same thing may be sai dof horses and cattle but with the difficulty that their voidings are not so evenly distributed as is the case with pigs and sheep.

Green manuring, or the ploughing under of some growing crop such as red clover on buckwheat, in the past, for improving the supply of organic matter in the soil; but unless on very low priced land the practise is of doubtful utility. We are usually deceived as to the amount of material that this adds to the soil. It takes an extra good soil to grow two tons of dry matter per acre; more frequently one-half ton is secured. Three tons of farm manure usually give over a ton of dry matter and after being properly spead are worth, probably more than a ton of dry in green manure. One objection to green manure is that where the soil is most in need of organic matter, the least quantity grows. The parts of the field that are richest get the heaviest application, just the reverse of what is desired. The same objection applies to farms as a whole. Those that are in the greatest need of organic matter cannot grow much of a crop of green manure. A manure spreader will apply the material evenly and at the same time give a heavier application, if desired, to the poorer parts of the field.

There are conditions, however, where a catch crop can be grown at very little extra cost; frequently for not more than the price of the seed. When this can be done it will be good business to do so, particularly if the land is greatly in need of humus.

It is very doubtful economy to spend a year raising a crop for the sole purpose of plowing it under. Such a practice may pay if no other plan is available, where organic mat-

ter is badly needed; but usually it pays better to pasture down the green manure crop, or harvest and feed it and return the manure. If pastured off in the field, all the roots and considerable of the tops are left where they grow, and 40-50 per cent. of the material that is eaten is returned to the land. There are some cases in which it is best to plow under a green manure crop, because it does not pay to keep animals to eat it, or because they might do injury as in an orchard; but, in general, it is best to either harvest, or pasture down the crop after it is gown. Hay is usually too valuable a material to use as manure.

In working out any plan for the maintenance of organic matter in the soil, it is well to always have in mind the fact that any kind of plant decaying and going back into the soil is a source of humus whether it be in the form of grass, weeds, manure, or from whatever source it comes.

KEEP THE POTATOES GREEN AND GROWING

Many are growing potatoes in Canada this year, for the first time and, as a result of the greatly increased number of growers the cop will probably be increased. But to insure a good crop there must be an abundance of moisture in the soil and the tops must be protected from insects and disease.

Cultivation—The soil should be kept cultivated with the cultivator or hoe until the tops meet sufficiently to shade he ground. As most of the tubers develop in the three or four inches of soil nearest the surface, and as the tubers will not develop well in dry soil, quite shallow cultivation is desirable at this season of the year. In soil which is dry there may be good development of tops but there will be few tubers. The roots in such cases have gone down deep into the soil to obtain moisture but the tuber-bearing stems, which are quite different from the root system, do not develop well. Where the soil is a loose, sandy loam, hilling is not necessary and may be injurious, as the soil dries out more than if left on the level. In heavy soils it is desirable to hill the potatoes as it will loosen the soil and the tubers will be shapelier than when the ground is left level. When there is sufficient rainfall and moisture in the soil hilling is likely to give best results in all kinds of soil, as the soil will be looser and the tubers can push through it readily. As a great development of tubers takes place during the cooler and usually moister weather of the latter part of summer, it is very important to keep the plants growing well until then. In one experiment it was shown that during the month of September there was an increase of 119 bushels of potatoes per acre.

Protection of Potato Tops From Insects.—It is very important to prevent the tops of potatoes from being eaten by insects, particularly by the Colorado Potato Beetle. The old "bugs" do not do much harm to the foliage, as a rule, and usually the plants are not sprayed to destroy these, although the fewer there are to lay eggs the less difficulty there will be in destroying the young ones. These begin to eat rapidly soon after hatching, and close watch should be kept so that the vines may be sprayed before much harm is done. Paris green kills more rapidly than arsenate of lead but does not adhere so well, and in rainy weather it is desirable to have something that will stay on the leaves so that they will be protected until it stops raining and thus prevent the tops being eaten. At the Central Experimental Farm a mixture of Paris green and arsenate of lead is used in the proportion of 8 ounces Paris green, 1½ pounds paste arsenate of lead (or 12 ounces dry arsenate of lead) to 40 gallons of water in order to get the advantage of both poisons. It may be that it is not convenient to get both poisons when either 12 ounces of Paris green or 3 pounds paste arsenate of lead (or 1½ pounds dry arsenate of lead) to 40 gallons water could be used, or in smaller quantities, say 1 ounce Paris green to 3 gallons or 3½ ounces paste arsenate of lead or half that quantity of dry to 3 gallons of water. An experiment conducted for six years at the Ontario Agricultural College, Guelph, showed that, on the average, where the tops were sprayed to kill "bugs", the yield was 186.9 bushels per acre, while when the tops were not sprayed and allowed to be eaten, the yield was only 98.2 bushels per acre. It is desirable not to stop with one spraying which usually does not kill all the bugs, but to spray several times, if necessary, so that as little foliage as possible be eaten.

Protection of the Potato Plants From Late Blight and Rot.—In some years the crop of potatoes is much lessened by the late Blight disease and when rot follows little of the crop may be left. It is, therefore, very desirable to prevent this disease from spreading. This is done by keeping the plants covered with Bordeaux mixture from about the first week of July, or before there is any sign of the disease, until September. Sometimes the first application of Bordeaux mixture is made before the potato beetles are all killed when the poison for them may be mixed with the Bordeaux. While the disease is not very bad every year it is well to be prepared. There was an average increase per year of 94 bushels of potatoes from spraying with Bordeaux mixture in three years.

The formula for Bordeaux mixture for potatoes is 6 pounds copper sulphate or bluestone, 4 pounds freshly slaked lime to 40 gallons of water. While the bluestone will dissolve more quickly in hot water; if it is not convenient to get this, it may be suspended over night in a cotton bag in a wooden or earthen vessel containing four or five or more gallons of water. The lime should be slaked in another vessel and before mixing with the copper sulphate solution should be strained through coarse sacking or a fine sieve. The copper sulphate solution is now put into a barrel, if it has not already been dissolved in one, and enough water added to half fill the barrel; the slaked lime should be diluted in another barrel with eonugh water to make half a barrel of the lime mixture. Now pour the diluted lime mixture into the diluted copper sulphate solution and stir thoroughly, when it is ready for use. The concentrated lime mixture should not be mixed with the concentrated copper sulphate solution, as, if this is done, an inferior mixture will result. If the barrels are kept covered so that there is no evaporation, stock solutions of the concentrated materials may be kept in separate barrels throughout the season. It is important to have the quantities of lime and copper sulphate as recommended, but, in order to be sure that enough lime has been used and there is no danger of burning the foliage, let a drop of ferrocyanide of potassium solution (which can be obtained from a druggist) fall into the mixture when ready. If the latter turns reddish-brown, add more lime mixture until no change of colour takes place.

HOW TO DRENCH SHEEP

Many people do not know how to drench sheep. Some roll a ewe on to her rump and pour the medicine down her so that it goes down, not only to her stomach but also into the lungs, choking her and causing a waste of the medicine. The best way is to take a two ounce syringe and place it in the back corner of the mouth. Be sure that it is above the tongue, and while you empty it hold the mouth closed. The liquid gathers in the mouth, and since it cannot run out it must be swallowed. If the ewe does not stand, back her into a corner and she will probably take the treatment very gracefully.

Often it is convenient to use a small necked bottle. A small sized olive bottle is very handy in this respect. In drenching lambs with gasoline for stomach worms, the gasoline can be mixed with milk and fed from the bottle very nicely. Usually the use of a bottle takes longer and is not nearly so easy, for if you have many to do you will lose your patience.

PURITY FLOUR

the Efficient Flour

The real baking foundation for white, even-textured bread; delicious, dainty cakes and light, flaky, mouth-melting pastry. High in food value and distinctively pleasing to the taste.

SPECIAL

The Purity Flour Cook Book

the latest publication on modern kitchen practice; a 180-page de luxe, general purpose, kitchen encyclopedia, carrying between its covers reliable and tried recipes for all manner of dishes for the ordinary meals, as well as economical instructions for the preparation of dainty desserts and delicious confections for special occasions.

Mailed postpaid on receipt of 20 cents.

CONFIDENCE IN BUSINESS IS A USEFUL TRAIT

In any business or profession confidence is a very useful acquisition to have regardless of whatever toher instruments one may possess as stock in trade for working out the various problems with which he is connected. A man that does not believe in his own ability and lacks confidence in it to "do things" is not likely to go very far afield in pursuit of his calling. There is not much in life's activities for such a one but to follow in the footsteps of other men and still further deepen the rut that has already grown too deep.

In order to succeed one must get a vision of his own and go out of the beaten path, if needs be, in order to work out the various problems connected with the solution of his enterprise.

Of course confidence must not be confused with conceit, with which there is nothing in common. The former is ever open to re-adjustment, to profit by the experience of others and to apply any known methods or deductions to one's own immediate needs in order to further the interests of his undertakings; while the latter is narrowed and dwarfed by the thought that he is a sufficiency unto himself and needs the help of no man to work out his problems; therefore by vain-glorious and foolish notions he stands in his own light and so closes all the avenues to success by refusing the very help that he needs because of his self sufficiency.

A conceited person is one of the most stupendous monstrosities in existence. Humility becometh all men. "No man liveth unto himself," said a wise teacher and he who knows it all, has no place in a democratic world.

It is only by getting outside of one's-self and using the brains and energies of other men as well as one's own that real success can be attained. It is not possible for any man to know any great part of the wonderful world in which he lives and the most that he does know or is able to glean is principally what the other man who has preceded him has found out. So must it ever be. "Line upon line," and "Precept upon precept," "Here a little and there a little" is the best way any one can hope to acquire of the vast world about him, and of that little the most of it from the experiences of other men.

While the young man then should practise self-reliance and have confidence in himself, in order to succeed he must be humble and willing to learn from any and all sources of information with which he comes in contact.

To make this matter practical the young farmer should not always grind away on the farm. He must get out into the world and see what others are doing. The way that his fathers trod may have been a goodly road for them, indeed the best road, but nevertheless it may not be a wise one for the son. The world is ever changing, and particularly during the last generation has it been changing very rapidly. The practices and methods most useful a generation ago are not the best for the present age; and so we must keep pace with the times in which we live. The whole truth in relation to agriculture has never been known; but we are getting a little nearer as the years go by. One farmer may have advanced along a certain line further than another while their positions may be reversed in something else. The way to get and to keep in the fore-front of the best up-to-date farm practice, is to get into personal touch with the leaders of the day and give one another a friendly life when the opportunity or need arises. With this end in view an occasional visit to one another's farms is good practice, where matters of general interest may be discussed, and notes on common farm practices and methods compared.

In a case of a young man beginning business or as a preparation for business a few months or a year or even more away from the home farm with some leader in the line in which he is most interested, or even with two or three such men, where he would have an opportunity to study their methods and so reinforce himself with the best available information would be on the subject of his deepest interest, time well spent. Then with the aid of the best and the latest teaching on the practical and scientific phases of agriculture kept before the public by the Farm press he should be in a thoroughly good position to launch out into his life's work with a good prospect of success if in addition to his experience gleaned in the way suggested he is able to bring to bear reasonable ability, good judgmnt, energy and severance.

THE OLD WAYS OF OLDEN DAYS MUST PASS AWAY

In connection with the present food scarcity, it is well to understand that there is no scarcity of land to raise the food on.

Scarcity of farm help is the great trouble, and is hard to remedy. Greater efficiency is the answer to the problem. There are scores of ways of applying it. The man unit has got to do more work; not necessarily work harder, but he must accomplish more, raise more bushels and pounds of farm produce. How is he going to do this?

On clean land, under ordinary conditions, it is a foolish waste of time, for one man to follow one plow bottom day after day, to the tune of one-and-one-half acres per day, and there are hundreds of thousands of farms in this country where this is the rule. Just think of it: One man spending a whole week to plow ten acres of land when he can by modern methods, with horse power, and two bottoms, plow the same in three days, or better still with the tractor, plow the whole ten acres in one day, by using a night shift. The trouble we are so used to the old methods, we think we must continue to follow them, and we need a jolt to wake us up. The jolt is here!

Poor crops are often the result of improper, or insufficient tillage, this is impossible where so much time is killed by not working to advantage, if we are so long plowing a field that the planting season is right on our heels, we do not roll and harrow thorough enough to obtain a proper seed bed, and we grow a poor crop, and lessen the production on the farm to just that degree. But the interest on the land coninues on just the same, and taxes are none the less; it is a dead loss. And this condition is an unalterable one; that it takes every bushel or pound of a crop up to a certain yield, to pay expenses, and there is absolutely no profit until that limit is passed, and every bushel or pound raised above that limit is all velvet, or nearly so, less the cost of harvesting and marketing at least.

This is a fact that is too seldom taken into consideration by the average farmer. We are too apt to associate efficiency with getting up early in the morning, and going to it until dark, day in and day out. You have all heard about the boy who had often heard his father say that it was "Half in Calculating," who was sent out with the team to work in the morning, and when about noon the father went out to the field to see how the work was progressing, found the team hitched to the fence and the boy perched on the fence, and when asked for an explanation repeated his father's proverb, and reported he was half done, having spent the entire forenoon calculating. I sometimes think the boy had the principle all right, maybe he applied it too literally; we do not figure enough.

Yes, each man unit has got to accomplish more results, and it is up to every farmer to devise ways and means for accomplishing this result.

* * *

Silage is succulent, palatable, and bulky, and has a good effect on the digestive system.

Buckwheat is a late-sown crop that deserves better attention than it receives.

The silo provides a means of keeping over, for summer use, feed of high quality.

One plows, another sows, who will reap no one knows.

* * *

Farm and Home published in Springfield, Mass., says in regard to the Red Cross Society:—"It is the one agency which will be father, mother, doctor and friend in need to every boy at the front or elsewhere in service. It will be America's aid to our Allies and to war sufferers in all lands."

* * *

Our farmers are not slackers; they are ready to serve in army or navy, in munition factory or ship yard, or on the farm in food production. They will go gladly wherever their country most needs them. Any of these places is equally honorable, brave, serviceable and patriotic. In most cases, the expert farmer can best serve his country on the farm, where he is so terribly needed at the present moment.

THE LAST WORD IN CANNING

How the Housewife May do Her Share in the Conservation of Food

By Ida Cogswell Bailey Allen in Pictorial Review

With thrift as a national watchword, there is no more important subject before American women this Summer than that of canning. We must plant for another year's supply, but we must can to save what we already have. This article deals with the newest and most carefully tested methods of canning, based on the most recent Government investigations.

The old days of the open-kettle method, with its doubtful results, have passed and the intermittent, or three days' canning method has also become a part of culinary history. The wise woman chooses the new cold-pack method which insures fine, firm, colorful results, products that will keep, all with a minimum expenditure of time and energy.

The outfit needed in carrying on the new method of canning is as follows: Agood wash-boiler fitted with a wire rack made to contain from six to ten jars, according to the size of the boiler, and equipped with handles so that the jar-filled rack may be removed without burning the hands; and wide-mouthed glass jars, preferably with covers that clamp on, altho screw-top jars may be used. The rubbers must be new and of genuine rubber to avoid tainting the products with a tar flavor; further there should be a steamer, or an improvised steamer consisting of a wide-topped kettle over which a steamer-top may be fitted to use in steaming greens and other bulky vegetables before putting them into the canning jars.

Commercial Outfits Are Good

Commercial canning outfits may be purchased if desired. The hot water bath outfit is especially made for out-of-door work and is equipped with a fire box with smoke pipe, sterilizing bath, lifting trays, etc.; it is quickly set up and light enough so that it may be easily transported from place to place. If a very large amount of canning is to be done, this outfit will more than pay for itself in the long run, but the results are no better than those obtained by means of the wash-boiler equipment already described. A second type of commercial canner is used as a water-seal outfit in which a higher temperature may be obtained than in the hot water bath outfits described, and which is particularly good in the canning of meats or certain vegetables which are difficult to keep.

Then there are the steam-pressure out-fits which are very practical and which may be used in the household as general cooking utensils. The first cost is a little high, but if one lives on a farm the cooker will pay for itself in short order. With these commercial outfits come adequate directions for their use, so, whereas in this article we are listing in our time-tables the periods necessary for the proper cookery of vegetables and fruits in the water-seal and pressure cookers we are devoting our space to special directions for the canning of fruits and vegetables in the home-made outfit.

Several new terms have come into being along with the new cold-pack method. The following list, with its definitions is self-explanatory.

1. Cold pack.—The packing of uncooked or blanched foods together with some liquid as sirup, water, soup-stock, or vegetable juice into clean jars, covering and then sterilizing or cooking them with their contents by means of boiling water or steam.

2. Scalding.—The dipping of a vegetable or fruit into boiling water to loosen the skin so that it can be removed with the least possible loss of pulp. Also to remove undesirable acids, and to start the flow of the coloring matter; this must be arrested immediately by the cold dip.

3. Cold dip.—The dipping of the scalded fruits or vegetables immediately into cold water for two or three minutes to arrest further cooking and, therefore, to harden the heated pulp. This coagulates the coloring matter so that there will be less loss of color during the sterilization period and, at the same time, the products may be handled to much better advantage in packing.

4. Blanching.—To boil or steam the product to be canned for a brief time before packing into the cans. Unless it is necessary to remove a strong flavor; as that of cabbage or dandelions, it is far better to blanch the tproducts by means of steam, as there is then no loss of food value. The process is necessary to remove objectionable acids and bitter flavors, to reduce the bulk of vegetables like spinach, and to obviate all necessity for the use of the old-time, intermittent process by which it was necessary to boil the fruit or vegetables in the jars for three days in succession, to insure the destruction of all germ life.

5. Sterilizing, or Processing.—These terms are used interchangeably and refer to the steaming or boiling of the filled jars for the purpose of destroying all spores, germs, and bacteria. Needless to say this is the most important part of the process, for if sterilization or cooking is not complete the canned goods will not keep.

To achieve good results in the home process of canning it is absolutely necessary to follow the directions carefully and to make sure that the products actually sterilize the right length of time. It is a very easy matter, for instance, to prepare a half-dozen jars of corn and to leave them sterilizing in the kitchen while work is being done in another part of the house. The fire may get low, however, and the jars actually sterilize by means of the boiling water only two hours instead of the necessary three. The corn [illegible] would [illegible] trouble [illegible] time [illegible] done, such [illegible] or soft berries [illegible] pleted [illegible] other [illegible] done in the kitchen.

Unless it is necessary to can in large quantities in order to utilize produce [illegible] in order to make money [illegible] products in quantities [illegible] done a few jars at a time in a kettle of moderate size equipped with a round wire rack to hold the jars. If two or three jars of each fruit and an equal number of vegetables are canned as the foods are in season, the housewife with a small family will find that during the period from May through October, she will have accumulated a wide range of canned foods at comparatively little expense and labor. The collection should begin with rhubarb, running the whole [illegible] out of the Summer fruits and berries through quinces and citrons. The vegetables may begin with asparague and continue through sweet potatoes and pumpkin.

Whatever the vegetable or fruit, the general processes of preparation and sterilization are the same.

1. Scald, or blanch the food according to the length of time noted on the time-table.
2. Dip in cold water.
3. Remove the skins if necessary, ermove any cores, blossom ends, stems, or stones, according to the nature of the food to be canned.
4. Pack into wide-mouthed jars as closely as possible.
5. Fill the jars almost full with the desired liquid and add salt according to directions, if needed.
6. Adjust the rubbers and tops and partially clamp them on, or, if Mason jars are being used, screw the tops down until they touch the rubber, but do not absolutely close the jars, as otherwise the expanded air can not escape and will cause them to crack.
7. Sterilize the required length of time, in water which will come to the rim of the jars.
8. Remove the jars, tighten the covers, and turn the jars upsde down on a cloth away from a draft, covering them with a cloth so that a sudden breeze will not cause them to crack.
9. After a few days, loosen the clamps and pick up the jars by the covers. If sterilization has been complete the covers will not come off as a complete vacuum will be formed. Clamp again and put the jars away after wrapping them in paper or cloths to assist in preserving the color.

Special Directions for Canning Vegetables

Allow a level teaspoonful each of salt and sugar to each quart of boiling water used in canning the vegetables. Substitute the juice obtained by boiling tomatoes for water in canning tomatoes. Use absolutely fresh vegetables. This is especially true of corn and peas. Scrub all root and tuber vegetables as carrots, sweet potatoes, etc., thoroughly with a vegetable brush, then [illegible] to remove the skins. In canning corn on the cob, remove the husk, silk, etc., and blanch the corn on the cob eight minutes for medium sized ears, five for small ears and longer for large. Re-steam it when taken from the can for serving, rather than boiling it a second time. In preparing corn cut from the cob, blanch on the cob, then remove the kernels with a sharp knife. String beans before blanching. Clean mushrooms, and if large cut them in

TIME-TABLES FOR BLANCHING AND STERILIZING

quarters. Clean greens thoroughly, then steam.

In canning either pumpkin and squash for pie fillings, steam until tender, then mash, add a cup of sugar and a teaspoonful of salt to each quart of pulp, then sterilize as directed. All vegetables and fruits should be graded according to size, so that the various pieces will cool through in the same time. This adds greatly to the appearance of the finished jar as well.

..Canning powders should never be used as they contain boric, or salicylic acid, which are drugs and have no place in foods. At the same time, their use is absolutely unnecessary, if care is taken in canning, and they are an additional expense. Finally, most of them contain ingredients which are prohibited, or forbidden in many States, and by the Government.

If desired, special seasonings may be added to the jars of vegetables along with the salted water; for instance, pickled young carrots are delicious. In this case a half cupful of strong vinegar, a tablespoonful of sugar, and a teaspoonful of whole pickle spice could be added to each pint jar of carrots. Pickled beets may be made in the same way. All kinds of greens may be canned according to the time-table given herewith. These include the edible wild greens as well, such as milk-weed sour dock, purslane, etc. In canning greens, cabbage, or Brussels sprouts, it is a good plan to season them by putting into the center of each jar a thin slice of fat bacon, salt pork, a little minced raw ham, dried beef, or olive-oil.

Special Directions for Canning Fruits

Fruits may be canned with or without sugar, but it is a saving of both time and fuel if a sirup composed of the proper proportions of sugar is used to fill up the can rather than plain water. However, if sugar is prohibitive in price, the fruit may be covered with plain water instead of sirup. In this case the unsweetened fruit should be drained from the juice before using, the right quantity of sugar added to the juice, and the whole boiled toegther for a few minutes, the fruit being added in time so that it may become thoroughly sweetened. By ths method, however, the fruit is always overcooked by the second heating, and, therefore, loses brilliancy, both of flavor and color.

Sirups of different densities or degrees of sweetness are used in the canning of fruits, the choice depending upon the tartness of the fruit and the richness of the result desired. The following table gives the amounts of sugar and water needed in preparing sirups of different percentages or densities; the sirups will hereafter be designated in this article by the density, or percentage:

Sugar	Water	Per Cent.
1 lb.	3 qts.	16
1 lb., 4 ozs.	3 qts.	20
1 lb., 9 ozs.	3 qts.	25
2 lbs., 8 ozs.	4 qts.	30
1 lb.	1½ qt.	32
2 lbs., 8 ozs.	3 qts.	40

General Directions for Canning Fruits

The general directions for canning fruits have been given earlier in the article. The steps in the process are the same as in the canning of vegetables, except that it is not necessary to always blanch the fruit. The same principles are applied; however, there are a few additional points that should be especially noted. The fruit should be fresh, firm, but ripe, entirely free of all leaves and stems, and absolutely free from rot, blemish, or mold. If gritty, as with strawberries, it should be thoroughly cleaned.

The skins should be removed from peaches, apricots, pears, oranges, apples, and quinces by blanching. Soft fruits which are of a sweet nature, like strawberries, raspberries, loganberries, huckleberries, or blueberries, figs, and wild and damson plums as well as grapes, need no blanching, but oour berry fruits, as currants, gooseberries, cranberries, and sour cherries ae better if quickly blanched. Pineapple and citron need longer blanching, because they are harder. It is not necessary to fill the can to overflowing with boiling water or sirup, whichever is to be used; it is enough to fill it to within a quarter of an inch of the top.

In every case where the skin, cores, or seeds are to be removed, the blanching and cold dip should take place before it is done, as otherwise there is liable to be considerable loss of flavor. The stones should be removed from peaches and apricots and the fruit canned in halves. If desired, one peach stone may be allowed to a jar to enhance the flavor. Pineapple should be pared, the eyes removed and the pineapple cut in convenient sections before blanching. Citron, cantaloup, and oranges should also be pared before blanching. The cantaloup will be greatly improved if spiced; in this case use a sirup made of five pounds of sugar, a pint of vinegar, a cupful of water, a half cupful of broken stick cinnamon, and a third of a cupful of whole cloves to seven pounds of fruit. Pears, figs, peaches and watermelon rind may also be pickled in sirup of this kind.

The sirups indicated in the table are of the sweetness used by the best commercial canners. If desired, richer sirups may be used, byt if this is done there is danger of introducing too much sugar into the dietary. If desired, apples may be baked, packed into jars, covered with a thin sirup of twenty per cent. and sterilized twenty minutes in the home water outfit. In this

Are you Working Your Head as Hard as Your Hands?

CANADIAN farmers face to-day the greatest problem—the gravest responsibility—the greatest opportunity that has ever come to them.

Three years of fighting has made food the one vital factor in the struggle. If the Entente Armies and the workers behind them can be kept well fed, victory is certain. To this "if" the farmer alone can supply the answer, "yes."

The problem is enormous, expressed in hundreds of millions of bushels of grains. The answer must come in the few hundred or even few score extra bushels which each individual farmer can manage to grow. Head work is needed to make the utmost of the limited supply of labor. Only be careful planning and better methods can the increases so urgently needed be made.

Every bushel added to the food supply available for 1918 will be a definite service to the Empire, and at the same time will bring its own reward to the grower—for never in this generation have crops brought such returns. Never has there been such a patriotic incentive to make big money, for

case the sirup should be boiled down and poured over the apples at serving-time. Canned, sliced oranges may be used for salad purposes and so may canned and quartered apples.

Preserves, suh as strawberry, raspberry, cherry, plum, etc., may be cooked slowly according to the usual methods, cooled, poured into jars and sterilized for twenty minutes with the home water outfit, or fifteen in a water-seal or five pound steam-pressure outfit; this is an extra insurance against spoilage. Fruit juices may be canned according to this general method with or without sugar, but the time of sterilization may be slightly lessened.

So far as possible, it is better to prepare, blanch, and pack one or two jars of a product at a time. This is especially true of corn, peas, beans, and asparagus. Care should be taken that unbroken vegetables and fruit be packed into the jars if appearance is to be considered.

Mold may develop if the seal is defective, or if the jar tops are removed to slip the rubbers back into position. If this is done the jars must be resterilized for five minutes. Mold may also appear if jars are kept in a damp place where the rubbers may decompose. The best water for canning purposes is pure, soft, and free from excessive quantities of mineral matter. the EDITOR'S NOTE:—With the importance of the conservation of food facing us as it has not done in many generations, it is for the women of our country to make this the greatest canning season ever known. The Government not only publishes valuable bulletins on canning, but, if you are unskilled, they will send an agent to your community. Write Miss Jennie A. Fraser, Truro, Supervisor Womens Institutes for Nova Scotia; Miss Hazel Winters, Fredericton, Supervisor Womens Institutes for New Brunswick; or Miss Hazel L. Stearns, Charlottetown, Supervisor Women's Institutes for Prince Edward Island.

THE FOURTH SPRAY

Written by G. E. Sanders and W. H. Brittain at the request of the United Fruit Companies

The season of 1917 has proven in many respects very similar to that of 1913, with abundant development of apple scab before the blossoms. Whether this will result in the elimination of the crop in the orchards not receiving the pre-blossom spray is still a matter of doubt. In any event the orchards that did not receive the pre-blossom spray or any spray, will suffer severe leaf injury and will bear very inferior, if any, fruit.

With the advent of the new spray gun, which has resulted in halving the cost of application of spray as well as wetting the trees more thoroughly than any oher spraying device heretofore invented, still more dilute solutions must be used than with the old ype of mist nozzle.

For the last summer spray we must have a mixture that will remain effective over a longer period than for any previous, for the blossom of the coming year depends on the trees retaining a healthy foliage until late in the season than on any other single factor.

Fourth Spray

Time.—Ten days to two weeks after the third spray.

Material—First Choice; Bordeaux 7-7-100, adding paste lead arsenate 5 lbs. to 100 gals. or powdered arsenate of lime 2 lbs. to 100 gals.

Second Choice; Lime sulphur 1.005 sp. gr. or 1 2-3 gals. to 100 gals. water, (1-60) adding 1¼ lbs. powdered arsenate of lime to 100 gals. water.

Application.—Use 200 lbs. pressure and a calyx nozzle or a spray gun.

Pests Destroyed.—Apple scab, Pit, rot, Fruit worms, Codling moth, Tussock moth, Fall webworm, Red-humped and Yellow -necked caterpillars and Fall feeding Browntails.

Ordinary Bordeaux mixture, somewhat weaker than ordinarily used is recommended for the last summer spray on account of its better sticking qualities, as well as on account of the fact that the ordinary Bordeaux does not cause dropping of the young fruit when used at this time. We have found that 7 pounds of copper sulphate and 7 pounds of lime (stone) to 100 gals. of water is practically harmless as far as the foliage and fruit are concerned, when used two weeks after the blossoms fall and later. The use of Bordeaux immediately after the blossoms fall will result in severe russetting, while the use of Bordeaux before the blossoms will also result in slight russetting of the fruit.

We find that almost any of the common poisons can be used with a greater degree of safety with Bordeaux mixture than alone. There seems to be no object in using Paris green on account of its high cost at the present time and danger from injury. Arsenate of lime, two pounds to 100 gallons, makes a very satisfactory poison with Bordeaux mixture, but the best poison for use on the apple is probably paste arsenate of lead. We tested out various poisons many times with Bordeaux and, with only one exception, the paste arsen-

DAIRYING.

DEHORNING OF CATLE

Eighteen Reasons why all Utility Cattle Should be Dehorned. By W. Fraser, Live Stock Commissioner For Manitoba

1. They are worth 40c. to 50c. per cwt. more live weight.
2. They make better cattle when matured.
3. They are more contented.
4. They are more kindly to one another.
5. They do not produce in the other animal a nervous, restless temperament by inflicting injury, often severe, as they do if wearing horns.
6. They produce more milk, since they are free from fear of each other.
7. They produce more beef for the same reason.
8. There is less danger to the people who have them in charge.
9. The bull, which sometimes kills his keeper, cannot do so if dehorned.
10. He cannot gore to death o horse or other animal, as is too often the case where the horns are on.
11. They can be housed in much smaller space, and kept more comfortable with less expense.
12. One animal cannot guard a doorway and keep the others exposed to the elements.
13. One cannot hook all the others from the water trough.
14. The shrinkage is much less in shipping.
15. They are not torn and bruised in shipping.
16. At least three head more cattle can be shipped in the same car.
17. A mixed lot of more or less inferior cattle will sell much more readily dehorned.
18. More and better cattle will be produced as a consequence.

The dehorning can be most satisfactorily done when the calf is but a few weeks old by the applying of a little concentrated lye or caustic potash to the young horn.

I respectfully request the co-operation of all interested in the cattle business in any way whatever to use their influence in making dehorning universal.. I am thoroughly convinced that it would increase the number of cattle to a very marked degree, and thereby increase our resources.

KEEP MILK PAILS ALWAYS CLEAN AND PERFECTLY SANITARY

In hand milking the pail used plays a great part in the production of clean milk. A pail with an opening larger than the lower part of the vessel gives the best opportunity of course for the milker to "hit the pail", but it also gives dirt of all kinds the best chance to get into the milk during the process of milking. Some pails taper towards the top, others are partly covered so that dirt does not have a good chance to enter and others have a hood extending so far over the top that it is almost impossible for anything to fall into them. These all have their advantages and everyone who does his milking by hand should exercise care in choosing the type of pail he can use to the best advantage. The more nearly the top is closed, the harder it will be to see that the pail is kept clean and a dirty pail may be a greater source of contagion than the dirt, hair, etc., which falls into the milk when milking.

A pail ought to have the seams filled with solder so that the inside of the vessel is smooth. It is easier to solder on the ouside and often the seams on the inside are left open and very soon after one begins to use the pail a yellow deposit of milk and cream settles there which ordinary washing will not remove. Here the microbes multiply between milkings and seed the warm milk with a crop of bacteria which soon causes the milk to change flavor.

Milk pails are sometimes made with double bottoms in order to prevent rusting. The inside bottom is made of zinc. This after a time gets a hole in it and then is becomes a veritable hotbed for propagating the microscopic plants. When the warm milk comes into the pail the air under the false bottom expands as will be noticed by the bubbles rising in the milk. When the milk cools the air under the false bottom contracts and milk is drawn between the bottoms where it can never be washed out. Here is putrefies and is a constant source of contamination.

I was acquainted with a case where a high.priced milk pail thus acted as a source of contamination for a long time before it was discovered where the microbes came from. When the hole was discovered it was impossible to get it soldered so that no milk could go between the bottoms until a hole was made in the outside one. Sometimes strips of zinc are soldered across the bottom of pails to prevent rusting by the unequal oxidizing power of the metals. Here the same thing is likely to occur and hide an enemy which is worse than a hole in the pail.

A fruitful source of bacteria in milk is the strainer. Brass strainers are sometimes placed on milk pails. These are often so filled with dried milk that the milk flows through but slowly. Often a cloth strainer is used and washed after each milking. If this is not washed carefully with cold water, then with soap or some good cleansing powder and warm water then thoroughly scalded it becomes a prolific source of contamination. The strainer after having been scalded should be hung in the sunshine to dry and air. The pail should be washed in the same way and then placed in the sunshine to dry and air. Everybody knows that it is of paramount importance to keep all utensils used in connection with milk as clean as possible at all times. Many of us, however, are very careless in this respect.

ACTUAL EXPERIENCE IN COW TESTING

The following experience in cow testing from a farmer, outlines some of the revelations which this simple practice brings, and notes the results which naurally follow a careful system of testing and weighing milk.

"I started to keep records about five years ago. The results were surprising, and the longer I kept at it the more interesting it got. The first thing I noticed was that at the least little disagreeable change of temperature, a cold rain, a snow flurry or a cold southeast wind, if the cows were kept in or had a shed to run in it made a difference according to the scales. Here are some other points: I never sprayed the cows for flies before I started weighing. Now I usually start to feed meal in the fall as soon as I notice by the scales that the yields are going down, and I also notice I am starting to feed a little earlier each fall. By watching all these things one gets the cows milking a longer period each season.

"The last two years I have had several cows milk almost up to freshening time again, in fact two cows a year ago and one last spring were not dry at all, had a calf and went right on milking. This should not happen, but in these cases I did not know the cows' calving time exactly. I believe by weighing the milk and careful watching of details one can get the cows up to a high standard of milk production. I think the scales instead of being a bother and taking too much time to weigh each cow's milk, are the best paying cows' in the stable, with only three or four dollars invested. We milk from twenty to twenty-five cows as a rule. At first I weighed the milk after each milking and afterward only twice a week, but I soon got back to each milking again, for when one weighs it twice a week he does not notice any drop in the yield quickly enough.

"By weighing and testing the milk I have certainly found out some very surprising things. I had a very rough looking cow with long, coarse hair, about as rough a looking cow as you could find and I didn't pay much attention to her as a milker. At the end of the first year of weighing and testing, her average test for fat was four per cent., and she gave nine thousand pounds of milk, so I considered she was worth keeping for a while at least. Another large fat cow was in a bunch I bought so I had to take her, but thought I would turn her over to the butcher. However, the scales told me I had better keep her, for she gave more milk on less feed than any cow I had and was fat enough for the butcher at any time. I also found out by the scales that different cows required different amounts of each kind of feed to get the most out of them. If you feed a cow what she likes best, whatever kind of meal it is, the scales will soon tell you if she is making returns for it. The first year of testing the two best looking cows in the herd, and, as I thought good milkers, were turned off to the butcher. The best looking cow last year went to a dealer. The scales are sometimes a bad thing for the look of your herd, as they are no respecter of looks. The best lookers are not always the best payers, and I believe the money spent on a set of scales and a four-bottle testing machine is money well spent. Moreover, the time spent in this work has been very interesting as well as profitable."

Sometimes a cow is difficult to milk because the opening in the teat seems too small. Get a milk tube, sterilize it and press into the opening so as to draw off the milk and stretch the orifice until it is large enough for a full flow. Sometimes a cow has a hard lump in the udder. Rub it every third day with a mixture of two drams of iodine in two ounces of lard until the lump disappears. Often when a cow is hard to milk or holds it up she will come all right from feeding a little bran or grain, as this diverts her attention from the nervous action which is the source of the trouble. When the calf comes, care in milking will prevent the milk fever. In case of attack pump air into the udder with a bicycle pump.

ACADIA UNIVERSITY
WOLFVILLE, - - Nova Scotia.
Departments
Arts and Sciences. Applied Science. Theology.
Degrees
B.A., B.Sc., B.Th., M.A., and certificates in Engineering admitting to third year in best technical schools. First year in Medicine, Law, and Theology given as electives in Arts course.
Equipment

This New Farm Boot

CHROMOIL TANNED BY

Palmer-McLellan

FOR SUMMER WEAR

POSTPAID TO YOU FOR

$4.50

The wonderful chromoil leather in these boots is a big improvement on the best ordinary "Oil-Tan." It is waterproof not only on the surface but all the way through. It does not dry out nor crack from heat, nor stiffen up quickly from frost. It retains through everything the soft suppleness that makes it so comfortable.

The shape, too, is n w and better, combining the easy comfort of the Indian moccasin with the permanent form of a regular boot. This is ensured by building it on a last, and giving it a solid extra long counter in the heel. It's a boot that will stand up to the hardest kind of service, in any weather, and outwear any other working boot you have ever tried.

At the same time, it is light in weight and easy on the feet, and remarkable value for the price.

If your dealer cannot supply you with these new Palmer-McLellan Chromoil Tanned Farm Boots, mail us the price and we will ship you a pair postpaid.

Men's Sizes	6	inches high,	per pair		$4.50

CREAM IS STRINGY

Bad odors and stringiness are produced from a variety of causes. Impure water is one of these; weeds another. Different kinds of food, even wholesome foods, often cause undesirable flavors. Cows too far gone toward freshening is a frequent cause of viscosity and odors; also disease, especially of the udder, such as garget mamitis or tuberculosis. We cannot tell the cause without a careful examination. One cow may cause the whole trouble. Carefully examine each cow's milk separately by taking samples and setting each in a glass or teacup, and allowing to stand in a warm place until sour, at the same time noting the smell of each daily. By carefully following up this plan you will soon find out the cause. Then remove the cause and you have the cure.

GRAIN FOR THE CALF

When skim milk is substituted for whole milk in feeding the calf, something needs to be added to replace the butter fat removed in the cream. Corn can be used to good advantage. It is better cracked than ground fine. Bran is good and ground oats are splendid. A mixture is better than just one of them. The calf will begin to eat feed when two to three weeks old, and should have access to it. The best way to feed grain is dry, and care should be taken not to allow any of it to remain in the corners of the feeding box, as it will sour and may cause digestive troubles. Boiled ground flax seed is also used with skim milk to make up for the fat removed.—North Dakota Experiment Station.

COTTAGE CHEESE

Skim milk can be made into cottage cheese which is a wholesome and nutritious food. Sour the skim milk, then set the container in a pan of water 100° F. or that feels warm to the hand, leave there 20 minutes, stirring occasionally. Then pour into a cheesecloth bag or salt sack and hang up to drain 5 to 10 minutes, work the curds until they become fine in grain. The addition of cream improves the flavor. Salt and flavor to taste.

Skim milk is not always used to its full value as the fat only has been removed. The other valuable nutrients are left and these are the tissue-building nutrients and so can to a large extent replace meat. In cottage cheese, these nutrients are brought into a more concentrated form.—North Dakota Agricultural College.

EARMARKING SMALL FLOCKS OF SHEEP

In most flocks of sheep, especially of pure bred animals, it is advisable to use some system of flock numbers aside from the registry number. It is easy for an ear tag to be lost out, but a good system of ear notches serves as an identification at all times.

The system used at the Colorado Agricultural College is one which can be recommended for small flocks. C. S. Anderson, in describing his method says: One notch in the base of the lower part of the left ear 1; two notches at the same place represents 2; one notch in the upper part of the left ear 3; one notch in the lower and one in the upper part, 4; and one notch in the point of the left ear, 5; one in the point and one in the base, 6; one at the point and two on the base, 7; one on the point and one in the upper part, 8; one in the point, one in the base and one in the upper part, 9. The right ear represents the tens, number ten occupying the same position as number one on the left ear. In breeding ewes certain markings such as holes in the middle of the ear can be used to designate the year of birth.

The system is only applicable to the small blocks of less than a hundred sheep. If one wishes to mark a larger flock, there is a more complicated system by which sheep numbering up to ten thousand may be ear marked. It is not commonly used. These systems can also be applied in the marking of cattle or hogs.

HOT WEATHER

the season when a

DE LAVAL SEPARATOR

saves most over any other separator or skimming system

IT'S A GREAT MISTAKE for any dairy farmer without a separator or using an inferior machine to put off the purchase of a New De Laval Cream Separator in the summer months especially with butterfat at the present unusually high price.

Great as are the advantages of the New De Laval over all other separators, as well as over any gravity setting system, at every season of the year, they are even greater during the mid-summer season than at any other time.

This is because hot weather conditions occasion greatest butterfat losses with gravity setting and render it most difficult to maintain quality of product with any gravity system or unsanitary separator, while, moreover, the quantity of milk is usually greatest, and any loss in either quantity or quality of product means more.

Then there is the great saving in time and labor with the simple, easy running, easily cleaned, large capacity New De Laval machines over all other methods or separators, which naturally counts for more at this time of the year.

Hence the great mistake of putting off the purchase of a New De Laval Cream Separator in summer, whether you already have a poor machine or none at all, and every dairy farmer should keep in mind not only that a De Laval will pay for itself in a few months but may, if desired, be bought on such liberal terms as to actually save its own cost while being paid for.

Every claim thus made is subject to easy demonstration, and every De Laval local agent is glad of the opportunity to prove these claims to you, in your own dairy, without cost or obligation on your part.

Why not see the nearest De Laval agent at once? If you do not know him, write to the nearest office for new catalog or any desired information.

Every New De Laval is equipped with a Bell Speed-Indicator.

Indigestion Resulted From an Inactive Liver

The Bowels Became Constipated and the Whole Digestive System Upset.

With many people constipation becomes a habit. And it is a dangerous habit which is certain sooner or later to cause serious disease.

"Daily movement of the bowels" is the first and most important rule of health. When the liver becomes torpid the flow of bile into the intestines is stopped and the bowels become constipated. But you can readily overcome this condition by using Dr. Chase's Kidney-Liver Pills. There is no treatment obtainable which so promptly awakens the activity of the liver and bowels and thereby corrects derangements of the digestive system.

Mrs. Herbert Doherty of Beaver Brook, Albert Co., N.B., writes: "I can truthfully say that Dr. Chase's Kidney-Liver Pills are a great medicine for constipation. I have suffered from constipation ever since I can remember, but got to using Dr. Chase's Kidney-Liver Pills and was so benefited that I began to study this malady. I found that the indigestion resulted from a bad case of inactive liver, and as soon as I got the liver working right I didn't have any stomach trouble or indigestion. I cannot praise this medicine too highly, and would advise anyone suffering from indigestion or constipation to use Dr. Chase's Kidney-Liver Pills. My husband also claims that these pills have done him more good than any medicine he ever used. You are at liberty to use this letter."

Dr. Chase's Kidney-Liver Pills positively relieve and cure torpid liver, constipation, biliousness, indigestion, backache and kidney disease. Put it to the test. One pill a dose, 25 cents a box, all dealers, or Edmanson, Bates & Co., Ltd., Toronto.

LIVE STOCK.

BUILDING SILO TO SUIT FARM

Could you give me a table of silo sizes and capacities, also an estimate of the cattle a given silo will feed, and the number of acres necessary to produce ensilage? J. H.

Most silo feeders now feed ensilage to stock fully six months of the year; many feed it the entire year. While the size of the silo can be determined almost correctly in each individual case, the following table of some of the most popular sizes, and the capacity of same, will prove of assistance to those who contemplate building a silo for the first time:

These figures are based on a feeding period of 180 days, feeding forty pounds a day, per head.

Diam.	Height.	Capacity in tons.	Cattle.	Acres
10	20	30	8	3
12	20	45	12	4
14	20	60	16	5
16	20	80	21	7

14	34	108	30	10
16	34	142	40	14
18	34	180	51	18
20	34	220	63	22
22	34	275	78	27
24	34	308	88	30
14	36	115	33	11
16	36	150	44	15
18	36	190	54	19
20	36	235	71	23
22	36	290	82	29
24	36	325	92	30

It may be remarked that the best current opinion favors the silo of considerable height. Silos up to 65 feet in height are now being built and good results are reported. It is hard to prevent waste of ensilage in a silo of large diameter.

EXPERIMENTS IN CONTROLLING ABORTION

The Health of Animals Branch of the Dominion Department of Agriculture has been conducting experiments with the object of ascertaining methods of controlling contagious abortion in cattle. The results of this work are briefly summarized in the following paragraphs, prepared by Dr. F. Torrance, Veterinary Director General for Canada:

Experiment I.—Four heifers, aged 1 year, were inoculated with our protective vaccine January 26th, 1915. The test of the blood of these heifers showed that one of them was already infected with the bacillus of contagious abortion, and all four were living in a herd in which the disease was known to exist.

The four heifers were bred on the following dates: April 21st, April 23rd, April 23rd and December 18th, 1915. They all calved, the dates being respectively January 26th, January 26th, January 12th and September 11th, 1916.

Experiment II.—Ten yearling heifers were inoculated March 20th, 1915, four of which reacted to the test for contagious abortion. They were bred after an interval of about three months. (Accurate dates cannot be given in this case, as the herd records were destroyed by fire). All became pregnant; eight carried their calves to full term and produced living offspring; two aborted.

Experiment III.—Four heifers, yearlings, were employed to test a method of employing a serum as well as a vaccine. With the first two, the serum and vaccine were used simultaneously; with the second two, the serum was given ten days prior to the vaccine. When tested, the first two had reacted to the test; the second two did not react. The first two were bred December 16th, 1915, and August 25th, 1915, and both aborted,—July 12th, 1916, and April 16th, 1916. The second two were bred December 23rd, 1915, and November 9th, 1915, and produced living calves September 20th, 1916, and August 5th, 1916. This experiment was unsatisfactory,

The Testing Time!

Russia Prospers

During the first eight months of Prohibition in Russia the Savings Banks reports show savings increased 5,000 per cent. (net).

WHEN the test of the world-conflagration called for every ounce of strength in every available man to stem the tide of destruction, one of John Barleycorn's greatest friends, Russia, was the first to abolish the Traffic because it could not meet the test. In good time, when her hour of test arrived, New Brunswick banished the great Drink curse let us hope forever!

After the war, in his turn, John Barleycorn is going to put New Brunswick to the test. Prohibition may again be voted upon after the war.

Every bit of lax enforcement and indifference is just so much ammunition for him to use against us. How does Prohibition meet the test?

Russia—

Some idea of the enormous effect of Prohibition is afforded by the wonderful example of Russia. In spite of the fact that millions of producers are in the army the savings of the people enormously increased. In 1912 and 1913 they were saving, per year, about $20,000,000. In the first five months under Prohibition they saved $60,000,000. In 1915 the banks took in $265,000,000. For the first half of 1916, the Russian people saved $300,000,000!

The Dakotas—

Town and city population in South Dakota under License increased 168 per cent. in 20 years. In the Prohibition state of North Dakota it increased 494 per cent.!

In "dry" North Dakota, for the year 1909, 2,789 men produced $19,137,000 worth of manufactured goods. In the "wet" Dakota it required no less than 3,602—***813 more men***—to produce only $17,870,000 worth of manufactured goods, or $1,267,000 ***less!***

In 1890 commitments to Insane Asylums in "dry" North Dakota were 40 persons per 100,000 ***more*** than South Dakota. After twenty years of Prohibition they were ***forty less!*** And the Prohibition State began the period with only about half the population of its neighbor!

South Dakota has since adopted Prohibition

Help to Enforce Prohibition

Permanent Prohibition in New Brunswick demands strict enforcement between now and the day when Prohibition may again be voted upon after the war. The whole task of enforcement must not be left to the officers of the law alone. Everyone should help. Eternal vigilance is the watchword.

BAD STOMACH AND CONSTIPATION

CURED BY

MILBURN'S LAXA-LIVER PILLS

Mr. Sylvester Clements, Galt, Ont., writes: "I wish to express my heartfelt thanks for what Milburn's Laxa-Liver Pills have done for me. I have been suffering from a bad stomach and constipation, and would be off work for 4 or 5 months a year. I was hardly able to be inside without getting a severe headache. I tried doctor's medicine and other remedies, but got no relief until a friend advised me to use Milburn's Laxa-Liver Pills. Now I can work inside without any headaches or pain. I would not be without your remedy for anything.

I write this so that anyone suffering the same as I did may use them and be cured."

Milburn's Laxa-Liver Pills are 25 cents per vial. For sale at all dealers or mailed direct on receipt of price by The T. Milburn Co., Limited, Toronto, Ont.

and gave conflicting results, but shows that the simultaneous method of giving serum and vaccine did not prevent infected heifers from aborting.

Experiment IV.—In this experiment an effort was made to find out how far the vaccine treatment would prevent abortion in cows which had previously aborted.

Eight cows were selected, ranging from two to seven years in age. All had previously aborted, one of them three times, the others once. All but one reacted to the test for contagious abortion. None were pregnant when inoculated nor bred afterwards until some weeks had elapsed. The result showed six cows produced living calves at full term; one cow proved to be barren and was slaughtered; and one cow reacted when the herd was tested with tuberculin and was slaughtered, having previously aborted.

The method used in this experiment was a double inoculation with a mild vaccine first, followed by a strong vaccine several days after.

Experiment V.—Four cows, aged two to seven years, and four yearling heifers were used. The cows had all aborted previously, one of them twice, the others once. Three of them reacted to the test for contagious abortion. All were treated by the double method, and were bred after a suitable interval with the following result: one of the cows, the one that had aborted twice previously, aborted again. All the others produced living calves.

These experiments have resulted in obtaining 27 living calves from 34 cows and heifers in badly infected herds. This encourages us to hope that we have a really useful method of producing immunity to the disease, and we are anxious to enlarge our experience by extending our work to other herds.

With this object, we now offer to treat free of charge a limited number of herds in which contagious abortion is present. Owners are requested to make application in writing to the Veterinary Director General, Ottawa, stating the number of breeding females in the herd.

Applications will be dealt with in the order of their receipt.

PARALYSIS IN HOGS

Azoturia of the horse, characterized by sudden paralysis of one hind leg or both, invariably is preceded by heavy feeding on a protein-rich ration during the spell of idleness. Active exercise and light laxative rations when there is no work for the horse to do, successfully prevents azoturia. Like measures of management are equally ncessary for the welfare of other animals.

Understanding the causes of azoturia of the of the horse and knowing preventive measures, we are in a position to view paralysis of hogs in a new light. It is now believed that one form of paralysis in these animals is similar in most respects to azoturia of the horse—that "going down behind" in heavy hogs and especially in sows that are nursing pigs.

It is commonly believed by farmers that such attacks of paralysis are caused by kindney worms. Postmortem examinations have proved that this idea is erroneous. Most of the paralyzed pigs show no trace of kidney worms while such worms often are found in apparently healthy swine. In some cases deep-seated abscesses are the cause, but in perhaps a majority of instances the causes are prolonged over-feeding with protein-rich rations, lack of exercise and constipation. The latter symptom is especially suggestive. It is seen also in hogs that are stuffed with corn and given little exercise and no laxative feed. It must be added that rickets in corn-fed hogs may have much to do with loss of power of the hind legs, and that the fat sow bred from highly fitted ancestry is most susceptible to paralysis, aggravated into actuality by the drain and strain of nursing pigs. Close observation has shown conclusively that constipation particularly and excess of protein in the ration of an under-exercised hog tend to induce paralysis. This belief is further corroborated by the fact that prompt purging with epsom salts followed by feeding on thin slop containing epsom salts or raw linseed oil, often leads to speedy recovery.

Prevention of paralysis is to be sought by stimulating activity of the bowels by exercise and laxative feed, and being careful neither to feed a protein-rich nor all-corn diet for a prolonged period.

next term, NOW is the time to send to us for full particulars, which will be supplied on application.

There is a great demand for young men and women to take the places of those who have gone to the firing line. Address:

W. J. OSBORNE, Prin.
FREDERICTON, - - N. B.

TO THE SHEEP MEN OF THE PROVINCE.

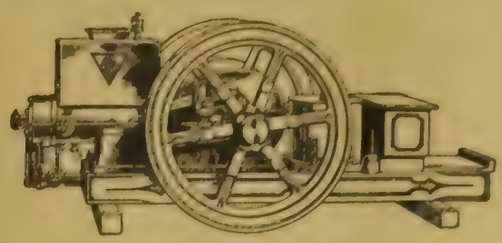
The Honourable J. F. Tweeddale, Minister of Agriculture for the Province of New Brunswick, realizing the fact that many of the sheep breeders and prospective sheep breeders of New Brunswick will be requiring breeding stock, both male and female, for the coming fall, and recognizing the fact that such breeding stock will become scarcer as the season advances wishes it made known that the Agricultural Department of the Province stands ready to help locate and put sheep men in touch with good stock.

The sheep industry should be encouraged in every way possible. The present prices of wool, mutton and lamb are such that every farm should carry its full quota of these money makers. "Stock up this fall with a pure bred ram and a few grade ewes" is a good slogan. The country is preeminently adapted for sheep production. Everything is just right. A new dog law, passed June 22, 1917, is very favorable to the sheep men's interests. The county council when petitioned by twenty-five men in the county, such men being householders and rate-payers, must pass a by-law declaring the dog law in force in that county. This is positive legislation. Legislation that will be beneficial in the widest measure to sheep men. It is up to the sheep men of each county to get up a petition with twenty-five names signed to it and the council will do the rest. Now the dogs may be taxed. These taxes constitute a fund for satisfying losses in the county caused by dogs.

Breeders of pure bred and grade stock are asked to co-operate with the Agricultural Department and supply us with the probably number of males and females that each will have available for sale. Persons desiring to secure animals for breeding purposes are asked to address all communications to Thomas Hetherington, Agricultural Department, Fredericon. This Department is at your service.

W. R. REEK,
Sec'y. for Agriculture,
Fredericton, N. B.

ALPHA



—the engine that takes the work out of farmwork

An Alpha will saw more wood in a day than you can saw by hand in a week

It will pump water all day long without watching.

It will run your separator, churn or washing machine.

It will run a thresher, feed cutter, or silo filler.

There will not be a day when you cannot find some way in which your Alpha will save time, money and labor for you.

Owning an Alpha is cheaper than hiring someone else's engine. The money you now have to pay out for engine hire when you need ppwer, and the greater amount of work you could do if you had an engine of your own would soon pay the cost of an Alpha.

The Alpha is a simple, powerful engine that will give you more reliable service and cause you less trouble than any other engine you can buy.

Ask for catalogue, prices and complete information. Made in eleven sizes, 2 to 28 H. P. Each furnished in stationary, semi-portable or portable style, and with hopper or tank cooled cylinder.

THE DE LAVAL COMPANY, LTD.

LARGEST MANUFACTURERS OF DAIRY SUPPLIES IN CANADA.

Sole manufacturers in Canada of the famous De Laval Cream Separators and Ideal Green Feed Silos. Alpha Gas Engines, Alpha Churns and Buttermakers. Catalogues of any of our lines mailed upon request.

PEERLESS PERFECTION

applies to our Poultry Fencing just right. It keeps your chickens at home—and their enemies out. Each intersection securely locked—the kind that stays "put."

Peerless Poultry Fence

is made of the best Open Hearth steel fence wire—tough, elastic and springy—and will not sag, break or weld under sudden shocks or quick atmospheric changes. Our method of galvanizing prevents rust and will not flake off or chip off. The joints are securely held with the "Peerless Lock" which will not work loose and allows expansion and contraction of the wire without injury. The fence is constructed on the most scientific principles, and thus ensures a neat appearance, lasting service and satisfaction. Write for catalog, Agents Wanted in unassigned territory.

THE BANWELL-HOXIE WIRE FENCE CO., Ltd., Winnipeg, Man., Hamilton, Ont.

Clean to handle. Sold by all Druggists, Grocers and General Stores.

THE HORSE

CHOOSE THE DRAFT SIRE BY THE HIGH CLASS VALUE OF THE COLTS HE LEAVES

The most difficult problem in draft horse breeding is that of the sire. In order to make any advance, to improve the horse stock to make the business successful, a high-class sire is necessary. To the man who is directing an extensive breeding establishment, this problem is not so serious, but to the average farmer who desires to raise a few colts each year, and who must depend upon a public stallion, it is a perplexing one. Fortunate is the community wherein can be found one or more really meritorious draft stallions that are available for public use.

Real high-class stallions are not plentiful. The country is over-stocked with inferior ones, or with those of fair individual excellence that do not beget their kind. The sort that sire colts that testify to the greatness of their sire are found only here and there.

The growth of the draft horse industry has been remarkably rapid, the demand for registered stallians sharp. To supply this demand it is natural that importers and dealers should distribute many ordinary stallions, and many, too that never should have been used as sires. A stallion's real worth cannot be ascertained except in actual service. Some of the good-looking ones, even well-bred ones, are disappointment as sires. Of course this is not the rule, but the fact remains that the true test is service in the stud.

The value of a high-class sire to a community is not represented in the price that is usually paid for him, though that may be high, but in the value of his progeny, or in the margin of value above the average of that for colts begotten by average sires. I know a community wherein a large number of draft sires are kept and 1,000 or more mares are bred each year. In recent years, one particular stallion in that community has sired colts that sold on the average from $50 to $60 above the average of prices received for the get of the other stallions. This means that this particular stallion was worth to that community something like $2,500 a year more than the average stallion, or for the term of his service, about 10 years, $25,000.

We must depend largely upon the sire for improvement in our draft horses. The average farmer will use the mares he already possesses for breeding purposes, and if wise will improve his brood mare stock by careful selection and elimination from his improved young stock. To make continuous improvement, he must have access to a good sire—one above the average. In the selection of such a sire, extra good judgment is required on the part of the farmer. If possible, he should seek for his use proved sires begetting colts that sell for prices above the average. Never be satisfied with average results. That will not get us anywhere.

If an untried sire must be used, one should be sure that he is sound, well bred, true to type, acceptable in conformation, and of sufficient size. If the farmer is doubtful of his ability to pass judgment on the stallions that may be available, he could wisely seek advice from men who are qualified to judge. He should seek the best stallion rather than the one offered at the lowest fee. It is poor business to save $5 to $10 on one end of the colt-raising venture and lose $50 or $60, or more on the other end of it. It is to be regretted that many farmers seem more concerned about the service fee than the merits of the stallion.

The difference between average horses and high-class ones is of such importance that men engaged in the business should not discount their chances for the maximum of attainment by using inferior sires. It is the extra $50 or $60 above the average price and the quality required to fetch the higher price that make the business profitable and attractive.

I am a firm believer in a community or company-owned sire, especially if no really meritorious stallion is available. The many mistakes that have been made in the organization of companies and the purchase of stallions have made this system unpopular, yet there is no reason why a number of business farmers cannot form a company and go about the purchase of a stallion in a businesslike way. I advocate the purchase of second-hand, tried sires where possible. It is not so difficult to find a stallion that has been used a number of years in a community that has proved to be a high-class sire and that may be purchased at a reasonable price. No mistake need be made in this manner of selection. The proof of the pudding is in the eating; the value of a stallion is represented by the colts he leaves. Study the colts even more critically than the stallion. If his colts are above the average in excellence he will be a profitable horse to buy, even though he may be along in years. It is much safer than to buy a stall-fed, over-fat hulk that has nothing to recommend him except beef and a highly colored pedigree. Pedigrees are necessary—stallions must be pure-bred—but performance is essential, too.

If it becomes necessary to purchase from an importing firm or a dealer great care should be exercised. Expert advice and assistance should be obtained by consulting a man who thoroughly knows the game. There are many thoroughly reputable and trustworthy men in the trade, but the selection of a stallion requires expert judgment and even with the best assistance mistakes may be made. Usually our agricultural colleges will give assistance willingly. If reputable firms are dealt with and the utmost care is taken, the results should not be so very bad. Beware of the over-fat stallion. Seek one that is thrifty, but not over-loaded. If a little thin in condition, his true form may be better judged. He will render better service in the stud also, if not too fat. At the same time avoid the hard keeper. If an imported stallion is desired it is as well to inspect him soon after arrival in this country. One will be able to judge of his form and endurance if he can see him soon after the severe strain of a trip across the ocean. Get one with a clean-cut head, well arched neck, a reasonably short back, wide loin, plenty of middle, a long hip, level rump, thick, strong thighs, well-muscled gaskins, clean, wide hocks, flinty bone, well-set pasterns of medium length, and big, tough feet. That conformation is standard. Alertness, docility, spirit, action, robustness, masculinity and other things that the clever horseman will see if the stallion possesses them, and will not see if he does not possess them, are points to be considered. Action is highly important. A straight, springy walk and trot, combined with a gay carriage, round out this horse into a desirable individual. Then if he is of a line of breeding that has proved worth while, if he has a line of ancestors that has made horse history, he is worth considering. W. L. Houser.

Be Safe!

Don't take too many chances with spavin, splint, curb, ringbone, bony growths, swellings and of lameness. Use the *old reliable* remedy—

KENDALL'S Spavin Cure

In the hands of horsemen, veterinarians and farmers for 35 years it has proved its worth in hundreds of thousands of cases.

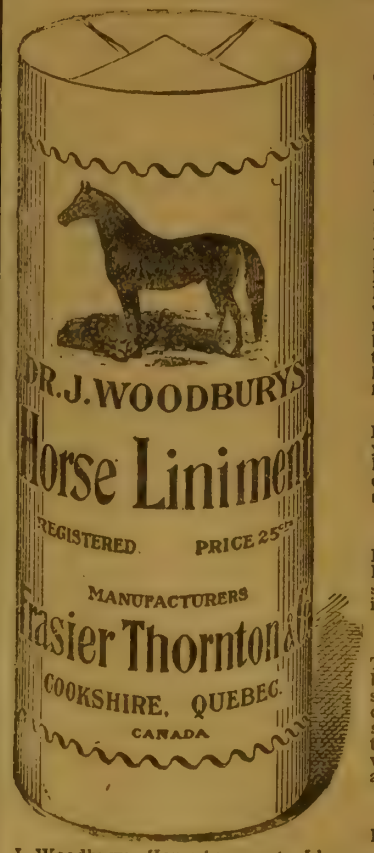
Dr. J. Woodbury's Horse Liniment

THE INFALLIBLE REMEDY



For the removal of Splints, Bog Spavins, enlargements of any and every description it has no equal. Given internally, it will promptly relieve and remove any and every character of Cough Enlargements of the Glands, Affections of the Kidneys. For distemper, strangles, and colic it is infallibly the remedy All horses that are stabled should have an application of Dr. J. Woodbury's Horse Liniment to the hoofs of the forefeet to prevent their becoming feverish, dry, brittle, hard, contracted or otherwise injured Insist on having Dr. J. Woodbury's Horse Liniment. We warrant it to effect that for which it is recommended when used according to directions. Its beneficial effects are so prompt and decided that it has excited the admiration of the leading horsemen of the Dominion and secured their highest confidence.

Bear River, N. S.
Dear Sirs:—We do not hesitate in recommending your Dr. Woodbury's Horse Liniment. We have used it in the woods for coughs, colds, distemper and cuts and would say that no lumberman should be without it.
Yours truly, Clarke Bros.

Hubbard's Cove, N. S.
Dear Sirs:—I have used Dr J. Woodbury's Horse Liniment in my stable for years and consider it the best liniment on the market for both internal and external use.
Yours truly, C. C. McLean.

Truro, N. S.
This is to certify that I have used Dr. J. Woodbury's Horse Liniment with the very best results for colds, coughs, distemper and all lung deseases. It is the best to give horses in the spring to keep them in condition. It purifies the blood, cleanses the lungs from impurities which may exist and gives the system healthy action.

Newton Lee, Owner "All Right" 5817.

Elmsdale, N. S.
Dear Sirs:—Kindly send me 6 dozen bottles Dr J. Woodbury s Horse Liniment. I have not a bottle in the store and it is the only kind my customers will take. Yours truly, Elmsdale Mercantile Co.

Elmsdale, N. S. Dear Sirs:—I cured my horse with Dr. J. Woodbury's Horse Liniment. It was a bad case of distemper. I always recommend this liniment to my friends as the best for all diseases of the horse. Yours truly, H. R. Whitehead.

Dear Sirs:—One of my horses had a bad cough and I made a complete cure with three bottles of Dr. J. Woodbury's Horse Liniment. The cough was of twelve months standing. In my large experience with horses I consider this liniment to be the best made for all diseases in the horse, I recommend it to my friends. E. J. Anderson, Truro, N. S.

THE CARE OF BROOD MARES HAS AN INFLUENCE ON THE LIFE OF THE YOUNG COLT

Essentially the care of brood mares is not different from that given to other classes of horses. The brood mare, however, represents, at least, two animals, and it is especially owing to this second animal that she becomes of extraordinary importance as compared with the other inmates of a stable.

Pregnancy in itself is a perfectly normal function which in no way interferes with the mare's health. In fact, it may involve a very advantageous influence upon the general well being of the animal body on account of the increased metabolism accompanying it. As a result we commonly see that during the earlier stages of pregnancy the mare shows a better appetite adn lays on flesh more rapidly.

During the first half of pregnancy, the condition of the mare is not different from that of the other horses of the stable, but after that time certain changes manifest themselves, which deserve our consideration.

As Pregnancy Advances

At that time the foetus has already assumed a considerable size and this for some time is still on the increase. The size of the foetus and incidentally that of the uterus is bound to exercise an influence upon certain organs and their functions in a purely mechanical manner.

The abdomen becomes heavy, so that standing and walking becomes less comfortable. The greatly increased uterus encroaches upon the digestive apparatus. The respiratory apparatus, likewise has pressure exerted upon it to the extent, that the animal shows a certain shortness of breath. At the same time, the increased activity of the body's vital processes increase the work of the heart and kidneys.

All those changes are far from being abnormal, even if they should be given full consideration in management. They may even be regarded as safety devices for the unborn colt. The sluggishness of the heavily pregnant mare, as well a sher shortness of breath are excellent factors in the prevention of excessively active movements or mechanical violence, which are apt to produce premature birth.

Provide Feed For Two

When we carefully consider the above mentioned facts and thereby not forget that the pregnant brood represents two animals when it comes to feeding time, the principal feature of her care and management are at once apparent.

In this the accustomed routine must be followed as near as the state of pregnancy permits this. The first question which presents itself here is the one of exercise and work. There can be no doubt that the amount of work performed by a brood mare during the last half of pregnancy must be considerably reduced. In the first place, because of the considerable part of nutritive material which formerly was available for the development of mechanical energy is now being utilized for the upbuilding of the new animal in course of formation.

Requiring a mare of this condition to deliver great amounts of muscular energy, which is, of course, primarily derived form the food, would be equivalent to the starving of the colt.

Working the Mare

The danger of this, however, is self-limited, as the labor efficiency of the heavy mare is already reduced by the size of her abdomen and her comparative shortness of breath. A mare can do a considerable amount of work with impunity, but it should not be forgotten that she must be used sparingly, must not be asked to draw too heavy a load or to go too fast a pace, while her condition as well as the welfare of the colt demand frequent breathing spells.

On the other hand lack of exercise would be as undesirable as too much of it. The body and the proper performance of its functions demand a certain degree of muscular activity and hence when we use our mares with some discretion there can be no objection to them performing their daily work. Many breeders work their mares almost to the time the colt is born and find it an advantage to do so. There is no doubt that such a course is preferable to confining the pregnant mare in a box stall and condemning her to inactivity for several weeks.

When suitable work cannot be found for the brood mare, she should be given the freedom of pasture or paddock.

Proper precautions must be taken to protect the heavy mare against external violence or injury. She must not be crowded into close quarters and certainly not in places where she is liable to be kicked or where she would be especially induced to do so herself. When used on the wagon or other implements, the jostling by the pole must be prevented. Care must be exercisd to prevent falls on slippery or icy roads. When used under the saddle the girt must not be drawn too tight.

Proper Feeding Important

Of great importance is the feeding of the mare. The fullness of her obdomen points toward the advisability of selecting a ration that is not too voluminous. Whatever feed, concentrated or roughage, be given, it must have qualities that count. The feed must be readily digestible and the kind, of whic the digestion is accompanied by considerable gas formation, be better avoided.

The practice of feeding horses only twice a day, which may be quite sufficient for horses not at work, must be condemned for brood mares, as it would require too large a ration at each meal. It is better to divide the food given per day over a greater number of meals. Spoiled or mouldy foodstuffs better be avoided.

While we cannot undertake to prescribe the most suitable ration at this place, we feel safe in saying that hay and oats must be regarded as the principal materials for the feeding of brood mares. A certain amount of corn can be used, while toward the close of the period of pregnancy the addition of wheat bran to the ration is very desirable.

The ration must not be deficient in proteid matters, while such minerals as lime must be present in the food in considerable quantity. In the feeding of the mare, she should not be permitter to fatten. The state of the body, such as we like to see in a horse fit for work is also the desirable one for a brood mare.

To Insure Good Colts

When the mare becomes a little constipated correct this by bran mashes, or a little flaxseed meal in the ration, rather than by the use of medicines.

After harvest get the poultry buildings in shape for winter use. Many farm poultry houses need remodeling, and a few dollars spent in doing this will be returned in extra eggs next fall and winter.

For best results pullets will have to be placed in the laying house early in the fall and not disturbed thereafter, so do not put off repairing their house.

DELCO-LIGHT
ELECTRICITY FOR EVERY FARM
Puts Joy in Farm Life

Do you realize what electricity on the farm means—clean, clear light any time of the day or night—without matches. Light all over the house, in the barns and sheds, in the yard, and dairy. Power to work the small machinery. Running water from an electrically operated pump.

It means doing chores in half the time. It means doing away with a lot of hard work. It means more fun, better health, *pleasure on the farm.*

And Delco-Light completes the joy of electricity on the farm, for it brings you electricity easily, economically. This truly wonderful plant costs little for the work it does. It is cheap to operate. Easy to operate. And gives splendid satisfaction.

Thousands of Delco-Light plants have been installed. Every owner is enthusiastic and feels that he paid little for all he has received.

The Delco-Light plant consists of combined self-starting gas engine and electric dynamo and a set of storage batteries. Starts on pressing of a lever, stops automatically when batteries are full. It is utterly simple in construction and operation. Efficient of fuel and delivers all the light and power you will require.

Full details, descriptive literature and a free demonstration can be obtained by writing your nearest distributor. They are listed below. The price of Delco Light is No. 208—$485 and No. 2[illegible] —$585.

POULTRY.

CULL THE FLOCK

(Experimental Farms Note)

The urgent need of conservation demands that all poultry not paying its way in either eggs or growth, be killed for eating.

The present high prices of feed also make the keeping of such classes of poultry decidedly unprofitable as well as unpatriotic. Therefore, for your own good and for the good of the country, kill them.

There are in every poultry yard birds that have outlived their usefulness and others that will never pay their way, these might profitably be finished and marketed, not necessarily all at once, but as soon as practicable, taking into account the market, etc.

In these classes might be mentioned, in the order in which they should be disposed of, the following:

1. **Male Birds.**—The breeding season being over, all males should be fleshed and killed. It will cost $2.00 or over to keep each male until next breeding season, therefore, get rid of them, it will also be better for the layers, the eggs and the growing chicks.

2. **Turkeys and Waterfowl.**—Toms and turkey hens, geese and ducks, not absolutely needed for next year's breeding should be disposed of.

3. **Hens.**—All hens of the heavier classes that are 2 years old and over might better be marketed now. In even the light classes many of this age ought to go. Others that are laying but that are not worth keeping for another year, should be kept until the egg yield does not pay for the feed. Better still keep culling out those that show signs of early moulting as you go along.

The best of the one and two-year-olds of the lightest breeds might pay to keep all summer, but only the year-olds should be kept over winter and even these will stand culling fairly closely.

4. **Broilers.**—If broilers are early, it pays best to sell the cockerels when two or three pounds in weight rather than to keep ill heavier. This is especially so when the sexes cannot be separated and where the runs are small, the pullets will soon require all the room and green feed available.

Light breed cockerels should be sold early; it seldom pays to feed them to maturity.

5. **Roasters.**—Don't leave the marketing of all roasters till late in the fall. Distribute this sale over as long a period as possible. Never market without finishing.

CHEAPER POULTRY FEED

On account of the scarcity and high price of feed the Poultry industry of this country is threatened by the prospect of the wholesale slaughter of laying stock and a serious falling off in the number of pullets to be matured.

The necessity for retaining for milling every possible bushel of wheat suitable for that purpose, need not be emphasized. To provide poultrymen with feed for rearing their young stock without unnecessarily lowering the supplies of milling wheat, the federal Department of Agriculture has requested millers throughout Canada to put on the market the cracked and shrunken wheat removed from grain before it is milled.

In addition to small and broken wheat, these cleanings consist chiefly of the seeds of wild buckwheat, a near relative of the cultivated buckwheat. The Poultry Division of the Central Experimental Farm has used wild buckwheat in feeding experiments, and reports it to be a highly satisfactory poultry feed and has ordered two cars of buckwheat screenings for the Central and Branch Experimental Farms from the Canadian Government Elevators at Fort William. Fowls used to good grain do not take to it at first, but when they become accustomed to it, they eat it readily and do well on it.

The mill cleanings from local flour mills also contain traces of many other weed seeds, including several kinds of mustards. These, however, would not as a rule amount to more than two or three per cent. of the cleanings in the case of the standard grades of Western wheat. This material is specially recommended for backyard, suburban and professional poultrymen. On farms the cleanings from yards and poultry houses where it had been fed, would have to be disposed of so as not to disseminate noxious weeds in grain fields.

Those interested in obtaining this class of feed should immediately arrange with local mills or feed dealers for a supply. The mills cannot be expected to keep this material for poultry unless it is demanded for that purpose, and that rests with the poultrymen themselves.

HALF-HATCHES

Mrs. W. S. M., is using one of the popular makes of incubators and does not get more than half a hatch. She wishes to know why chicks in an incubator die in the shell after becoming fully formed and ready to emerge.

If this correspondent averages a chick for every two eggs which she puts in her incubator she does about as well as the average. I have visited poultry plants in the east where hatches of as many as 20,000 eggs were made at one time. I have asked dozens of the incubator operators at the big plants what their average hatches were, and almost invariably they had told me, "About 50 percent." I have used incubators for nearly 30 years, having operated most of the better known ones. I believe that my average hatch has not been higher than a chick for each two eggs. Just lately I had the best hatches I ever had from one of the same make of incubator as this correspondent uses. I had 75 fertile eggs in the machine and got 66 nice chicks. At another time this year, using a well-known standard machine, I got 44 chicks from 140 eggs. From this same machine I once got 105 chicks from 120 eggs, of which I raised 95 to maturity. I use five different incubators and so far this year my average has not been more than 50 percent. A neighbor who is an accomplished incubator operator told me yesterday that her average this year was between 40 and 50 percent.

I do not know why chicks in incubators die in the shell, while eggs from the same flock hatch well under hens. It was once thought that an excess of carbon dioxide in the incubator killed the chicks. Careful tests showed that there is invariably more carbon dioxide under a sitting hen than in an incubator. I have quit theorizing. Even 50 percent hatches in incubators are more profitable than the average hatches made with hens.—Miller Purvis.

A ROUP-INFECTED FLOCK

A subscriber in Colorado keeps Black Minorcas of high quality. A year ago she bought a cockerel which was infested with roup. Now the entire flock is infected. From the description the disease has gone far. The prominent symptoms are cankered mouth, swollen head and charges from the nostrils and dark colored combs and wattles. This correspondent has been working a year to combat the disease and it has grown worse all the time.

The thing that needed doing first was neglected, a common failing in treating poultry diseases. When a fowl in a flock shows symptoms of any disease the proper thing to do is to isolate it, keeping it entirely separated from the remainder of the flock. The second thing to do is thoroughly to disinfect the poultryhouse. Thorough disinfection does not mean spraying a little coaltar derivative here and there in the house. It means cleaning the house by removing every bit of dirt and dust that can be removed by ordinary means. The floor should be cleaned and the walls swept with a broom. Then with a strong solution of any sheep dip or other coaltar disinfectant spray the whole inside of the house until it is dripping wet, using a solution double the strength advised on the container.

In this flock the most severe forms in which roup appears seem to be present. The cankered mouth is fowl diphtheria, the swollen heads denote catarrh and the discharging nostrils indicate true roup. At this stage I feel confident that the disease is beyond control. I watch my fowls for the least symptoms of a discharge at the nostrils. Twice during the past winter I found hens with swollen faces. I noticed this indication of catarrh before the swelling had made any great progress. The first symptom is watery eyes. Immediately I isolated these hens, gave them a dose of coaloil and squirted some into their nostrils and into the slit in the roof of the mouth and painted the swollen side of the face with tincture of iodine. If there had been any canker I should carefully have washed the cankered surface with a saturated solution of copper sulphate (blue vitriol), taking care that none went down the throat. One of these cases got well immediately. The other not yielding to treatment at once, the hen was kill-

For heavy tangled fields trust your

FROST & WOOD BINDER

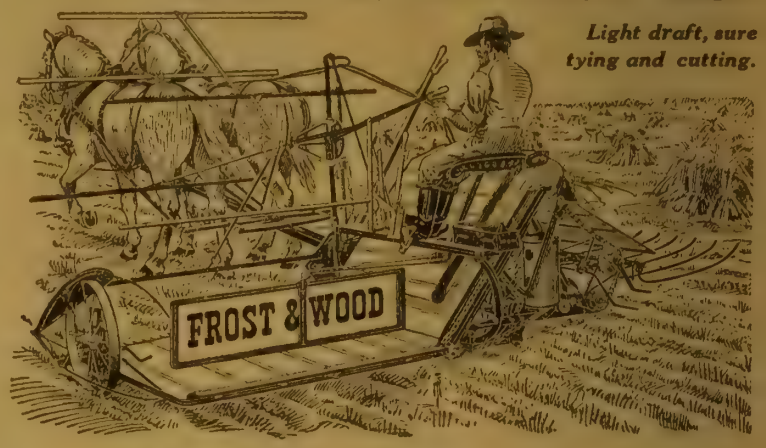
Many binders will cut grain that is standing nice and clean, but for tangled, heavy, rough and tumble cutting you certainly need the strength and light draft of the Frost & Wood Binder.

The Frost & Wood Binder is built of the toughest, strongest, yet lightest materials that money can buy. We use roller-bearings at every friction point, which makes long life and easy work. The elevation can handle any crop, no matter how choked or heavy.

Big power wheel, strong bracing, improved cutter bar construction, and many other good features. You ought to have our new catalogue at once and make a careful study of the Frost & Wood Binder.

Don't take chances with your crop. See our nearest dealer at once, or write us to-day for catalogue.

Handy levers work the reel to any position and bring the grain to the cutters. The Frost & Wood Knotter is very simple, and get-at-able. Needs no adjusting and it won't fail you.



Light draft, sure tying and cutting.

The sheaf compressor and ejector is worked by a smooth-running eccentric sprocket that does its work without jerking or strain. Hardly know it is at work—easy on the binder and the horses!

THE FROST & WOOD CO., Limited,

Truro ST. JOHN Charlottetown

Suffered with Kidneys

Could Hardly Sleep.

No woman can be strong and well unless the kidneys are well, for when the kidneys are ill the whole body is ill.

Doan's Kidney Pills are a specific for all kidney troubles. They begin by expelling all the poisonous matter from the kidneys, and then heal the delicate membranes and make their action regular and natural.

Miss A. Parks, East Middle La Have, N.S., writes: "For three years I suffered so with kidney troubles I could hardly sleep at night. I used all sorts of kidney medicine; some helped me for a while; others, which I gave a fair trial, did not help me at all. I was very sallow and had puffing under my eyes. I made up my mind I would try Doan's Kidney Pills, and on taking two boxes I found I was getting better, so I kept on using two more, and to-day I don't know I ever had kidney trouble. I owe all the praise to Doan's Kidney Pills."

"Doan's" are put up in an oblong grey box; the trade mark "The Maple Leaf"; price 50c. per box, at all dealers or mailed direct on receipt of price by The T. Milburn Co., Limited, Toronto, Ont.

ed and burned, as I could not afford to risk infection with so many hens on the place.

A friend of mine who is given to experimenting took several hens that he had cured of bad cases of roup and tested them for egg production. Not one of them ever produced enough eggs to pay for keeping her. He concluded that once a hen has been badly infected with this disease her usefulness is ended. Besides she no doubt would transmit to her progeny a tendency easily to fall victim to the disease. I believe I could have stopped the disease in this flock when it first started. I do not believe that any one can do so now.—Miller Purvis in Breeders' Gazette.

CAUSE OF LOSSES IN YOUNG TURKEYS

For many years those who had reared turkeys have had occasion to consider that the young birds are delicate to rear o naccount of the losses by death before they are seven or eight weeks of age, and as the result of their dying off during this early period there is a popular belief that after they have "shot the red" they can be considered to be safe.

This term is applied to the development of redness in their face, after which the youngsters look much healthier than they do before, and until this has taken place many turkey-rearers regard their birds as unsafe, and with great care fetch them in when it rains so that there may be nothing to retard their progress, but in spite of this numbers have succumbed. For some time we have been investigating this matter, for on account of the large number of young birds which have seen suffering from tuberculosis in an advanced stage, we came to the conclusion that there must be a cause common to each case, for although the birds have been sent in from all parts of England and Ireland, the conditions of their organs have been identical.

It has been quite clear that nothing in the feeding of young stock six and seven weeks of age could have developed tubercular trouble, for there was not the time to do it, so that the cause must be sought apart from the feeding of the youngsters, which had died on account of—

(1) Tuberculous liver.

(2) Tubercular deposits in the intestines, and

(3) Lungs which showed the perforations associated with phthisis.

On investigating the different cases we found that the young birds were not brought up on the same food, for nothing could have been more varied than the diet adopted by the various rearers, and yet the appearance of the youngsters was identical.

We have, through these columns, explained the actions of freshly mixed soft food on the organs of the hens which had this year after year, and when the whole of the energies of the digestive organs are utilised in assimilating foods which require a large amount of digestion, they become overworked, and in course of time the kidneys do not throw off the effete matter as they should, and this leads to the development of the tubercle disease germs, for it is only on impurity that these thrive, so that until poultry-keepers fully realise the necessity of keeping their birds' system free from this they have not grasped the fundamental principle of healthiness for their stock.

It may be suggested that doses of aperient medicine given at regular intervals might be beneficial in the removal of impurity from the system, but while these would partially cleanse the organs they would not remove the cause of the trouble, which can only be done by keeping the liver and kidneys healthily active the whole time, and by taking care to avoid overworking these, for as soon as they have too much to do they become clogged by the excess of urea, which sets up the condition everyone should avoid.

Many readers have adopted our pre-digested system of soft food for their turkeys as for their fowls, principally because it was easier to mix all the food for both classes of stock at one time, and by doing so they have ensured the healthiness of their young turkeys, for there have been no signs of any liver or lung trouble amongst those bred from the stock so fed.

The satisfactory progress of the youngsters is assured only when the parents are perfectly healthy, and unless turkey-breeders are careful to ensure that their are fit to hatch from, they are doing a grat deal of harm to those who purchase sittings from them. As next season's results in rearing young turkeys depend primarily on the condition of the stock birds, we regard it as of vital importance that each one should be put on pre-digested food prepared with the right ingredients now, for we have proved unmistakably that it is possible to entirely eradicate the taint of tuberculosis disease from ordinary hens and from turkey hens, just as it is from stock ducks, by providing food which enables the birds' organs to get rid of all the impurities on which the development of the disease depends.

Looking back over the years we have kept turkeys and the different conditions under which the young birds have been reared, we feel that it is quite possible to put stamina into the flocks by eradicating the taint of disease through their food, for by diverting the energies of their principal organs to promoting vigour instead of having to assimilate every particle of food, this can be built up.

The stock turkeys should have no maize at all, but for the evening feed just the best short oats all the year round, while their morning food should be exactly the same as we advise for the fowls, and they must be liberally fed on this, as they get a great deal of nutriment from this without the exhaustion following the assimilation of the old-fashioned soft food, and while a constant supply of sharp flint grit is necessary all the year round, it is only essential to provide them with ground oyster shells from February until they stop laying, as they need shell-forming material during this period.

We trust that all farmers and owners of turkeys will without delay put their birds on to the pre-digested system of soft food, and so ensure a flock of healthy youngsters for next year.—Mark Lane Express.

CROP-BOUND CHICKS AND CLOVER CHAFF

Some of the poultry breeders may be interested in the experience we have been having with chicks this spring. The trouble began when our chicks were three weeks old. They would droop around, not eat and showed every sign of cholera. I examined one and found something hard in the crop. I tried to crumble it between my thumb and finger, but it was a solid mass. I cut a small hole in the crop and found a large cockle burr. I removed the burr and sewed up the incision. I kept the chick penned for a few days and now we cannot tell it from the rest.

Later on we found many more with the burrs in their crops. Some would pass through and others would lodge in the passageway to the gizzard. The chicks would drink water and it would run from their mouths. They would finally die. Most of those that underwent the operation with the knife lived. The ones that burrs lodged in the esophagus gaped like chickens with gaps.

The chickens got these burrs in the clover chaff which we had been throwing into the colony houses. We had also used some of the chaff for bedding for the horses, and the burrs were hauled out with the manure and placed around the apple trees, where the chickens had access to them. We took rakes and had a general cleaning up, but occasionally a chick will find a burr yet. Many people have told me chicks could not swallow a burr, but these had passed through the clover huller and many of the prickles had been removed.

Probably this account of our experience will help others who have similar losses of chicks.—W. W. H.

TIT-BITS FOR THE POULTRY-KEEPER

Keep every early-hatched pullet for egg production next fall and winter, when eggs will be high.

Late hatching is permissible this year if the late-hatched chicks are used to increase the country's meat supply.

Late-hatched pullets will not make early winter layers unless given exceptionally good care.

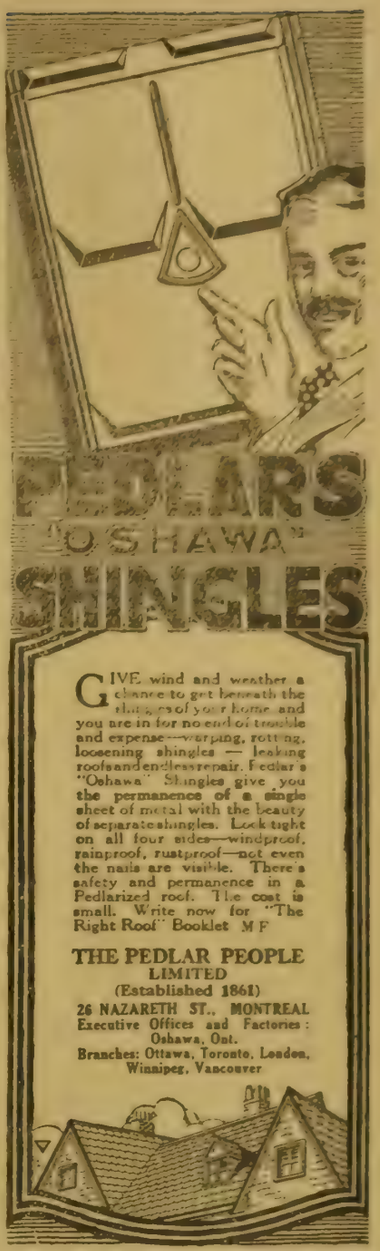
Keep all hens until about September 1. It does not pay to sell laying hens in the spring or early summer, for their eggs are of more value than the few extra cents per pound obtained at this time.

Do not sell early-hatched cockerels as broilers under two or three pounds in weight.

Sell all old roosters, so that every egg produced this summer will be an infertile egg. Doing this one thing will save thousands of dozens of eggs, usually spoiled by hot weather because they are fertile.

Caponize late-hatched cockerels to put on the market next winter, when meat will be scarce.

Take good care of the summer eggs. See that they are gathered daily from clean nests, and kept in a cool, sweet cellar until sold. Sell at least twice a week in hot weather, and insist that they are bought on a quality basis. Know that every egg you sell is a good egg.



PEDLARS
"OSHAWA"
SHINGLES
GIVE wind and weather a chance to get beneath the shingles of your home and you are in for no end of trouble and expense—warping, rotting, loosening shingles — leaking roofs and endless repair. Pedlar's "Oshawa" Shingles give you the permanence of a single sheet of metal with the beauty of separate shingles. Lock tight on all four sides—windproof, rainproof, rustproof—not even the nails are visible. There's safety and permanence in a Pedlarized roof. The cost is small. FOR HOME AND COUNTRY

This Department will be utilized to the best interests of the homes in the Maritime Provinces. Subjects relating to household science and all that stands for better homes and communities will be published on this page. The editors, Misses Saunders and Winter, of Fredericton, N. B., solicite your assistance in making this page a success and will be glad to publish tested recipes, household discoveries and other articles useful to the homemaker and women's organizations.

THE SONGSTER

"Music, music with throb and swing,
Of a plaintive note, and long;
'Tis a note no human throat could sing
No harp, with its dulcet golden string,—
Nor lute, nor lyre with liquid ring,
Is sweet as the robin's song.

"He sings for love of the season
When the days grow warm and long,
For the beautiful, God-sent reason
That his breast was born for song.

Calling so fresh and clear,
Through the song-sweet days of June,
Warbling there and whistling here,
He swells his voice on the drinking ear,
Of the great, wide, pulsing atmosphere,
Till his music drowns the day.

He sings for love of the season
When the days grow warm and long,
For the beautiful, God-sent reason
That his breast was born for song.

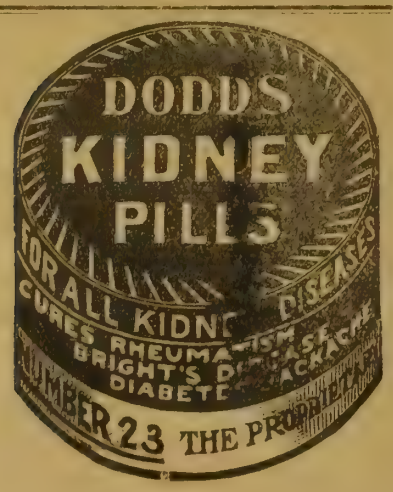
E. Pauline Jhonson.

HOME ECONOMICS
HOUSEHOLD MANAGEMENT AND BUYING ECONOMICALLY

This study has arisen from the desire to cut down household expenses and to get rid of household cares. We know that boarding houses are less expensive sometimes than real homes and by patronizing these the responsibility is shifted and the home loses ground. For most people the home is the beginning and the end of life. All their activities proceed from it and return to it. Therefore, of all the arts those pertaining to home making are the most important and of all the sciences those which find their application in the home, making us intelligent about the home and its needs, are the most significant.

Home making is universal; that is, there are workers of all classes and intelligences engaged in its occupation. But the woman who is the most successful in making a home is in every sense engaged in a learned profession—the greatest one on earth. For she has to initiate, plan, direct and carry out operations which involve in greater or less degree all the sciences and arts known to man. She also deals with those subtle spiritual powers which make or mar his personal happiness and influence his soul's salvation.

Housekeeping should be ranked as a profession instead of a trade. One who works at a trade does an assigned work planned by someone else who resumes the responsibility. A housekeeper is a director of home, she plans the work and looks after the spending of the money. This must be a business and requires qualifications. The woman who considers this work as an opportunity to assist in sharing the responsibilities of the wage earner has grasped the truth concerning the possibilities of her work.



Unfortunate is the home where the practical experience all comes after marriage. It comes at the hardest of periods and is unjust to any man. In no business can failure be graver or the results more serious. The fact that some very efficient housekeepers have evolved from unpromising beginners is no argument, such are without exception, most eager for their daughters to receive training, since they know by dear experience, its value. Our grandmothers, many of them, were beautiful housekeepers and splendid mothers. They learned their lesson in the hard school of experience and with the price of much unnecessary suffering. The young women of today has no excuse for answering "not prepared" when life demands that she assume her place as homemaker. Can anyone feel that this important work should be undertaken at marriage by girls who rely for preparation upon chance occupation at home supplement by the much abused "mother instinct?" There should be no more question as to the need of education and training for the woman who selects the food, clothing, and works of art which minister to the highest welfare of a family, than there is for the need of study on the part of the farmer, manufacturer, or the artist.

Much of the present aversion to household duties would vanish before adequate preparation to preform them. It is very true that when one's knowledge of a subject has passed the stage of drudgery and becomes a science its performance immediately becomes a pleasure. The essential thing for all to learn is to love their work, to see its possibilities as well as its difficulties, and to make their work their servant instead of their master. This can be done by the homemaker as well as by the physician.

Advantage of The Home

From an economic standpoint the instutional way of living is cheaper, but there must be the home, for the individual must be sustained and the Anglo Saxon civilization not degraded.

Independence of character and personal resourcefulness are now needed in the social world and the place for cultivating these is in the home. The life in the home trains for life in the world and leads to consideration of others, suppression of selfishness and stimulation to industry. Our conclusions are that the individual family must be maintained, but in a manner consistent with modern progress. To many the home has become a staying place, storing place or place of drudgery, and enjoyment is sought outside the home. These are wrong conceptions. In the home there must be wise expenditure of money, time and energy. Economics includes the getting and the spending of wealth. Woman is the main spender, or should be, therefore she should understand her work. She must realize that money has a limited purchasing power and she must think of what is necessary, not what is desired. A woman may spend $5.00 and get very little value from her money. The prosperity of a home depends just as much on the spending of the income as the size. Be careful at all times to get the greatest possible value for money spent. It shows lack of professional ability to spend money lavishly, for anyone can do that, but it requires the trained woman to spend money wisely. A study of economics will enable a spender to know where to economize and where to lavish.

Important Factors in Spending Any Income

It is necessary to know what constitutes good food, clothing, furniture, etc. The three most important factors that must be considered in spending any income are food, clothing and shelter. Of course different people have different standards regarding the amount to spend on each.

Food is the most important avenue of expenditure and has a direct influence on each individual. A well nourished person enjoys their work and they add to the general good of the public. Also they are less likely to take disease as the blood is richer in red and white corpuscles that fight against disease.

Correct food habits should be formed in infancy, that is, liking of proper food and not over feeding. There is just as wide a field to prevent sickness as bringing about a cure. The study of foods should give a cure to a large extent.

The amount spent on food does not determine the amount of nutritive value received by the family. One family spent $2.16 on oranges and $3.00 on celery. From this they obtained 150 grams protein and 6445 calories of heat. Another family spent the same amount for cereals and fruits and obtained 375 grams of protein and 184185 calories of heat.

Ways of Wasting Money on Food

By buying more than is necessary of perishable food.

Buying poor materials because they are cheap.

Buying foods out of season, they are very expensive and have not the same flavor or food value and home production is not appreciated when in season, and it teaches people to acquire a craving for foods hard to obtain.

By buying staple things in small amounts when it is cheaper to buy in larger.

Carelessness in keeping supplies after obtained.

Poor cooking, means a loss of food value, the food is less digestible and less attractive.

By carelessly leaving large amounts adhering to dishes.

Serving people more than they can eat.

The need of right buying and right cooking is evident since the body must be kept in repair, making it less susceptible to disease. It is necessary to know the value and understand the composition of our most common foods anyway. The cheapest diet is the one into which cereal grain foods enter most largely, also the cost is greatly increased when shell fish and chicken broilers take the place of dairy products and our ordinary meats.

Outside Preparation

A few points that are worthy of special notice are concerning "outside preparation". The cash expense of supporting a family is greatly increased through the transfer to outside hands of much cooking that was formerly done at home. Take for example, bread making. A barrel of flour 196 lbs. will make on the average 170 loaves of bread. The bread costs the consumer $17.00 whereas the flour can be bought for $7.50 per barrel.

(This statement would be different now owing to the high price of flour.)

Again, using breakfast foods ready for the table instead of the cheaper oatmeal, cornmeal and hominy that were cooked at home. The so called breakfast foods are sold under a steadily increasing variety of names. Now these foods are prepared in a hygienic manner, are not as a rule adulterated and are so thoroughly dried as to keep well, and in general may be considered to be among the very best of foods carrying a high proportion of carbo hydrates. It is the claims that are made for such extensively used materials and the wide differences in their cost, that render it advisable to consider the real facts touching their nutritive value. As the process of manufacture has not rendered these preparations greatly unlike, the cereal grains from which they have their source, except in some of them to dextrinize part of the starch, we must look to their digestibility for any increased nutritive efficiency which they may possess. The most reliable figures available do not show that breakfast foods differ essentially in digestibility from cereal flours and meals and certain home made preparations. In fact the digestibility of breakfast foods is proved to be in no way superior to that of granulated corn meal, oatmeal, or any of our home cooked cereals.

It is clear that the claims made for certain breakfast foods such as "the nourishing of more persons for a given time than other foods do" "The most natural food for mankind," "the great brain and muscle food," "the system will absorb a greater amount of nourishment from 1 lb. than from 10 lbs. of meat, wheat, oats or bread," are false, and the manufacturers making these claims either intend to deceive the public or are ignorant of the real nutritive value of their produce. The fact is it is not possible to so transform the nutrients in cereal grains or in meats as to materially enhance their nutritive efficiency, nor can such foods be "condensed" excepting as water is dried out. Cooking and malting may increase slightly the ease and rapidity of digestion, but for persons normal in health and function, there is nothing in the process applied to breakfast foods superior in any respect to home cooking.

It may be argued that cooked food is cheaper than hired help and is even a necessity where help cannot be obtained. Certainly the groceryman and the baker contribute to the ease and comfort of housekeeping,

but these surveyors of prepared food must be paid for their services, and heavy cash payments are in this way substituted for home labor. Many families do not realize how much is paid for the preparation and distribution of food before it comes into the house. One remedy is to buy more largely from the producer, the other remedy is home preparation of foods when reasonably possible.

Store Rooms.

Now a large proportion of homes have storage places where it is possible to hold flour, sugar, vegetables and fruits in good condition. When this is the case families may safely arrange to buy directly from the producer in barrels or bushel lots, a winter's supply of potatoes, apples, beets, etc. Flour should be bought by the barrel. Canned goods are cheaper by the case than when sold in packages, and any supplies are cheaper bought in bulk as you do not have to pay for the package and for the extra time spent in putting it up. The consumer is the one who pays this tax. Several families may unite to great advantage in buying supplies. No money can be invested at a higher rate of interest than by purchasing food material in considerable bulk.

Another important question in home economics is the planning of the house so that time and strength may be saved. It is said of the people of this continent that they spend too much on bric brac and too little time on keeping it clean. It is always unwise to have a great deal of fancy woodwork in a house (even with hired help). Plain surfaces are much more easily kept clean. The kitchen is perhaps the most important room as it is the work room of the house, it should be well lighted and ventilated. The day for large kitchens has passed and the modern up to date kitchen is small with all the working apparatus very compact. The more compact the working apparatus the more easily the work is done. A few extra steps count up very quickly in a day and thus unnecessary strength is expended. The pantry should be adjoining the kitchen and it is very convenient to have the pantry between the dining room and kitchen. Swinging doors are convenient, but do not have doors that require pushing to open. A swinging door should swing easily. A door that requires pushing, a sink that is too low, a low chair instead of a high stool, walking up steps to go from one room to another, any unhandy arrangements in the house help to weary and break down a woman more than we realize.

No one can make hard and fast rules for others, and though there are general rules of thrift and economy that apply to any household, each family has its own problems, its likes and dislikes and conditions as varied as their tastes. Needless to say it takes experience to manage a house economically.

The department of household economy which can be applied most nearly to all is the care of clothing, table and bed linen. If the housewife realizes the value of "the stitch in time which saves nine," she will save many dollars also. Months have been added to the wear of every piece of household linen as well as wearing apparel by prompt darning of thin places as soon as discovered. Even bath towels last many weeks longer, after five minutes on the sewing machine has strengthened the weak places. Given suitable thread and a little care, anything may be easily, quickly and neatly darned.

Most women understand that the things that are really extravagant are the things they can easily do without, as over ornamentation of the home or person and expensive entertainments. These can be left to those who have larg means or who have not learned that real happiness cometh not that way.

The most comfortable home one can afford, books for entertainment and help in mental growth, the refining influence of music, whatever help is needed to conserve the housewifes strength for things of greater moment—all these seem necessary to the higher standard to which we all have a right and the privilege to aspire.

THE WOODSTOCK WOMEN'S INSTITUTE

The last meeting of the Women's Institute of Woodstock for the year was held Wednesday, June 27th.

Roll call consisted of helpful and economical hints. One member spoke of a patriotic society in the United States collecting old rubber tires. The proceeds were used to keep their hospitals at the front supplied with hot water bottles.

The President, Mrs. Ellis and also the Secretary-Treasurer, Mrs. King, were elected for another term of office. Ms. Ellis expressed rgret that so little had been done and hoped for the coming year we might see greater results.

Mrs. King's report was very satisfactory and comprehensife. Eight regular meetings have been held and one special meeting.

During the year money had been raised and expended for various purposes. The Boy Scouts had been enabled to buy a tent. Yarn had been bought and socks contributed to the Red Cross and Soldiers' Comforts.

A letter was read from Miss Winter along the line of economy.

Rev. W. C. Kierstead of Fredericton gave a very interesting talk on Social Reform. He pointed out the responsibility of women in preventing the spread of disease. There were seven thousand more deaths in Canada from typhoid, whooping-cough, tuberculosis and measles in one year than occurred in the expeditionary force in the same length of time. The authorities ni Great Britain had cut down the death rate sixty per cent among children, in one year. The Board of Trade anti-toxin can be obtained very much cheaper than the ordinary anti-toxin. This in the province of Ontario is provided free.

The speaker called our attention to the condition of the prisoners in our own jail and lock up and bade us get interested in our own conditions and see what other are doing.

In Fredericton a great work is being done looking after neglected homes and the families therein.

DAINTY TEA GOWNS

The feminine eye cannot fail to be attracted to the dainty new tea gowns and boudoir gowns, which were never more lovely than they are this season. There is a distinct revival of the essntially feminine, daintily tinted boudoir gowns of flesh colored georgette crepe or crepe de chine combined with a coatee of wide, sheer lace flouncing. Occasionally georgette crepe is used beneath the flouncing to give the coatee a little more stability.

WHEN A DRAWER STICKS

If a drawer sticks, rubbing the bearing parts with a cake of laundry soap will usually overcome the difficulty. The saem treatment applied to the slides of extension tables now and then will work wonders. When reed furniture becomes soiled, it can be made to look like new if thoroughly brushed with a dry, stiff scrub brush and given a coat of dark golden oak varnish.

No one has ever been able to explain why bald headed men have their hair cut oftener than other men.

Now a

Fine, Bonny Little Boy

Penetang (Ontario) Child, Once so Thin and Delicate, Cured by Dr. Cassell's Tablets.

MRS. JARVIS, BOX 286, PENETANG, P.O., ONTARIO, says: "It is a pleasure to write and tell you what Dr. Cassell's Tablets have done for my baby. When only five months old he was taken ill. I had medical advice for him, and was told he had colic, for which he was treated, but he did not get any better, only worse. I tried several special foods, but none of them would stay on his stomach, and he became so thin that he seemed just skin and bone. He only weighed ten pounds. We never thought poor baby could live, but one day I chanced to hear of a baby's case almost like mine, that had been cured by Dr. Cassell's Tablets, so I got some for my baby, and I am thankful I did. After a few doses the nervous jumps he had suffered from stopped, and soon he was almost well. I have given him the Tablets during teething, and find them very soothing. He is a bonny boy now, quite cured, and weighs twenty-five pounds at twelve months old."

Baby Jarvis.

Every mother should know that Dr. Cassell's Tablets are just as suitable for children as they are for grown-up people. Their splendid nutritive and vitalising properties soon overcome any tendency to nervousness or weakness in the little ones, and lay the foundation of a strong constitution for after years.

Dr. Cassell's Tablets

FREE SAMPLE.

On receipt of 5 cents to cover mailing and packing, a generous free sample will be sent at once. Address: Harold F. Ritchie & Co., Ltd., 10 McCaul-street, Toronto

Dr. Cassell's Tablets are Nutritive, Restorative, Alterative, and Anti-Spasmodic, and the recognised remedy for

Nervous Breakdown	Sleeplessness	Mal-nutrition
Nerve Paralysis	Anæmia	Wasting Diseases
Infantile Weakness	Kidney Trouble	Palpitation
Neurasthenia	Dyspepsia	Vital Exhaustion

Specially valuable for nursing mothers and during the Critical Periods of Life.

Sold by Druggists and Storekeepers throughout Canada. Prices: One tube, 35 cents; six tubes for the price of five. War tax, 2 cents per tube extra

Sole Proprietors: Dr. Cassell's Co., Ltd., Manchester, Eng.

Two Cents a Word.

This department is one of the most valuable in the MARITIME FARMER. At a cost of only 2 cents a word, you can advertise anything you wish to buy, sell or exchange. The address must be counted as part of the advertisement and each initial or a number counts as one word. Cash must accompany each order and advertisement must have address on, as we cannot forward replies sent to this office. Copy must be received not later than Friday before the date of issue, which will always be found on the editorial page of the proceeding issie. No black faced type or display of any kind will be allowed under this head, thus making a small add as noticeable as a large one. The rate for this column is 2 cents a word, each insertion. MARITIME FARMER, Sussex, N. B.

LADIES WANTED to do plain and light sewing at home, whole or spare time; good pay; work sent any distance, charges paid. Send stamp for particulars.—NATIONAL MANUFACTURING CO., Montreal.

FOR SALE—Pure bred registered red Shorthorn Bull, Parkhurst Boy No. 101226, calved June 11th, 1915; milking strain; excellent individual; nice disposition from line of first rate performers. For further information apply to W. E. READ, Bear River, N. S.

Fir Shade Farm Dual-Purpose Shorthorns !

Several years ago I imported from Ontario three Dual-Purpose Shorthorn animals, and now have in my stable at Rothesay eight representatives of this breed. Two of the females are entered in the Record of Performance, and so far have done excellent work. If you feel disposed you might drop in and see these the first time you are in the vicinity. Perhaps some time when you are coming to the city you would let me know, when I could arrange to go to Rothesay with you.
P. R. L. FAIRWEATHER. St. John, N. B.

BULL CALF FOR SALE !
Born June 7th

Grandson of schurley Sir Posch with 21 pound bucking more white than black. A dandy at $45 F. O. B. any station in N. B. with papers.
WALTER PAYNE.
Lake Edward, N. B.

THE FOURTH SPRAY

(Continued from page 591)

ate of lead remained in suspension longer than any other poison used with Bordeaux.

In regard to lime, the fresher and cleaner the stone lime the better are the results.

For those not inclined to go to the trouble of slaking lime, the commercial hydrated lime is a convenient and satisfactory substitute. It is sold in powdered form and can be stored for weeks in the air without deterioration. For the greatest speed and ease in making Bordeaux we would recommend the following formula:—

In a cask or tank dissolve 1 lb. of copper sulphate to each gallon of water the tank contains. This is the stock solution and it may be made up several days in advance of spraying.

Seven gallons of stock solution should be placed in the spray tank for each 100 gallons capacity. The tank should then be filled up and 1 lb. or more, of hydrated lime added for each gallon of stock copper sulphate solution contained, the solution being rapidly agitated as the lime is being added. **All Bordeaux should be tested with litmus paper before being applid.** If the paper turns blue on being applied to the solution the mixture is right, if not add more lime until it does turn blue. Add the poison and the spray is ready to go on the trees.

We anticipate a slight amount of russetting this year from this spray. The longer the spray can be deferred the less russetting will result. After the down has fallen from the young apples there is practically no donger from russetting.

In case weather conditions are bad or one is anxious to avoid the slightest trace of russetting, lime and sulphur may be applied at about 1 gallon of concentrate to 75 gallons of water following this in a week or ten days with the Bordeaux according to the calendar.

For those inclined to experiment one or two tanks of the Thomsen-Buchanan Bordeaux, consisting of four pounds of bluestone and twenty pounds of lime to 100 gallons seems promising. Recent investigations in France also go to prove that a great excess of lime makes the full amount of bluestone unnecessary and makes a Bordeaux that is infinitely more lasting as well as safer on the foliage and fruit. The Thomsen-Beuchanan Bordeaux used throughout the season of 1916 resulted in the best crop of fruit produced in Nova Scotia during that season, what it will do in an adverse season remains to be seen.

Tile drainage is another way of deepening the soil and increasing the pasture ground of the feeding roots of the crop.

If it's in the line of progress, nothing can stop it, though many things may delay.

Exercise is as essential to the health and breeding quality of an animal as cultivation is to the growth of a paying crop.

Brantford Gasoline and Oil Engines

Stationary, Mounted and Traction

We manufacture the most complete line of Engines on the market. Send for Catalogues.

Matters of Interest to Maritime Farmer Readers.

THE HUSBANDMAN AND NATIONAL SAVING

An urgent appeal to the people of Canada has been issued by the Prime Minister for assistance and cooperation in securing the harvest, that no portion of it may be lost.

This appeal is timely, and while directed mainly to the securing of Canada's grain harvest, we of the Maritime Provinces must answer also the appeal to save and put to its best use all that has been produced.

Special attention should be given to the securing of a sufficient quantity of seed stock for the next year's crop, for under the continued stress of a greater production policy, an abnormal demand is occasioned for greater quantities of seed.

Seed of very inferior grade was used in large quantities during the past season, and to avert a repitition of the wastage and annoyance incurred, the crop producer should do his utmost to the secuirng of adequate seed supplies of his own growing.

The reserve seed supply of many staples is exhausted. Importations from Europe of vegetable and field root-seeds have virtually ceased, while with a continued campaign for greater production in Canada and across the border, it is anticipated that Canadian and Americn Seed Houses will have difficulty in furnishing an adequate supply of high grade stock. Farmers are advised in consequence to depend mainly upon local production.

Canadian Seedsmen are already looking to Maritime Canada to furnish a portion of the field root seeds required for Canada's root crop, and if our farmers would appreciate the advantages to them which the present situation of the seed trade offers, a profitable industry would be developed. For instance, the production of turnip seed. This crop has been grown in a small way for several years past quite successfully, and growers in Nova Scotia have developed a considerable trade in this particular class of seed.

In commercial root-seed growing the immature roots are used to produce the seed crop, and these are produced from seed sown late in the summer so that roots rarely exceeding three inches in diameter are produced. By this method a greater supply of seed plants can be secured at lower cost, than when large or stock roots are used. Of course, the young root shows neither its good qualities nor its weak points to the same extent as a full grown root, yet its usefulness as a seed producer is not impaired.

When harvesting these young roots "stecklings" so called, those which are deformed or having more than one neck are discarded; the tops cut off about an inch above the neck and stored in a cool cellar or pitted, where conditions are favorable, good drainage of the pit being one of the essentials.

Prompt Action Solicited

These roots are set out the following spring in rows made by drawing out a shallow furrow and planted about eighteen or twenty inches apart, in the row, and the furrows three feet apart. The soil should be rich, well drained and if possible, sheltered from heavy winds. Acid phosphate should be used freely as a fertilizer.

The roots should be planted firmly, and be set so deep that the crown barely reaches the surface, then when the furrow is thrown back they should be well tramped in, just so the crown reaches the surface of the ground.

The seed-yield secured by local growers, ranges in the vicinity of one thousand pounds to the acre, frequently exceeding this.

The Dominion Subvention on Home Grown Turnip Seed has been increased this year to fifteen cents per pound, and Seedsmen are placing contracts at thirty-five cents per pound, which with the subvention, nets the grower fifty cents per pound. An estimate of five hundred dollars per acre is thus given as the value of the acre yield.

An opportunity is here afforded the resourceful grower to engage in a new and profitable industry. Growers have for so long depended upon outside seed supplies that the production of root seed is a new phase of Agricultural practice, but so many changes and adjustments have become necessary in our Agricultural practices and industrial usages to meet the exigneces of war time, that we are learning dependence in our own resourcefulness, and if our production of food supplies is to be maintained, then crop producers must adopt this new phase in national saving and save seed supplies sufficient for their needs.

Never before has such an opportunity been afforded for the production of garden seed, yet unless amateur gardeners anticipate the next cropping year, their harvesting season will have passed and the saving of their seed supply will be overlooked. The first fruits of the garden should be allowed to ripen for seed, by this method the quickest growing plants are secured, and the tendency to acclimatization in our garden plants thereby assisted.

To facilitate the sale and exchange of seed grain among farmers and Agricultural Societies, the Department of Agriculture will maintain a Directory of the names of local seed growers. The Department is ready to assist in the formation of seed centres that the benefit of the cooperative idea in the production and marketing of seed stock may accrue to a community.

The individual grower has difficulty in working up a large and satisfactory trade, whereas working in cooperation with many others of the problems by which he is confronted cease. No community has ever made a success of any business or in any farming operation when all of its individuals attempt to produce a different line or type of product. A community makes a success and a reputation for its goods, because its members know how to produce goods of equal quality and uniform type such as the market world knows and recognizes as of value. The whole community is thereby benefitted, for the market looks to that community for that staple product.

With proper administration and management, the seed centre, no matter how far from the market, will find that unity in its efforts of production and marketing of seed stock, will bring the members better prices for their product and reduce the cost of putting their product upon the market. These features have been attained by different seed centres throughout the various provinces during the past few years, and as a result of their activities, "production more than usual" has been greatly aided.

The establishment of seed centres for the production of improved types of staple crops grown in this province, will quickly accomplish these objects, and in consequence increase the amount of exportable food products.

There is an urgent demand for more growers of seed stock, that we be not confronted in the near future with that dread of the husbandman, a barren harvest due to a scant seed supply.

Waste of time, opportunity, labor or food is sin. Let not our sins find us out in the matter of failing to ensure our future harvest, through failure to save an adequate supply of seed.

A thoughtful reflection upon these facts will make clear to the seed grower his vital part in the scheme for National Saving and his duty to the Empire as a food producer, by securing from his own fields the seed supplies of which the country will soon be in (such dire) need.

O. C. HICKS,
Dept. of Agriculture,
Fredericton, N. B.

NOTICE TO THE LIVESTOCK BREEDERS OF NEW BRUNSWICK

The demand for all classes of pure bred stock in New Brunswick is so great that it is doubtful if our local breeders can fill the orders that are pouring in to the Livestock Branch of the Department of Agriculture. Some time ago we forwarded a circular letter to each of the breeders in the Province, asking him to report the number of stock he had for sale. The response on the whole was very good, and to those men who forwarded a statement we have been able to direct a number of purchasers to them. However, the demand for stock is greater than the supply and the Department of Agriculture may have to make an importation from one of the other provinces.

The Minister of Agriculture, Hon. J. F. Tweeddale, insists that we exhaust our own local supply before making an importation. This he considers the best way to encourage local breeders.

To those men who have not yet forwarded a statement of their available stock to the Department of Agriculture, we ask you to do so now.

In parenthesis, it might be said that this is not an opportunity to dispose of any cull stock that may have been accumulating. The real purpose is to help farmers secure genuine breeding stock from New Brunswick breeders.

Breeders who have surplus stock of good quality for sale, will find it to their advantage to advertise.

SHEEP BREEDING IN NEW BRUNSWICK

New Brunswick farmers are beginning to appreciate the possibilities existing in this Province for sheep breeding. Hundreds of inquiries are being received at the Live Stock Branch of the Department of Agriculture for information on this subject. Very many of these men contemplate making a start this fall, and very many of them in starting are laying their foundation with pure bred stock. This is as it should be. Start small but start right. Some may not be able to buy anything but a pure bred ram and some common ewes. This means that the ram must be a good one or else the lambs will suffer. A sturdy blocky, active masculine ram means a good bunch of hearty lambs next spring.

To those men who are engaging in this busines for the first time, as well as those who are about to go into the business on a larger scale, we wish to state that the Department of Agriculture is at your service. We will be pleased to aid you in any way possible. The beginner should start in a small way unless he has had previous experience. Sheep seldom do well on low, wet land. Unless you have a dry upland pasture you will have trouble sooner or later. Select the same breed as your neighbor. Do not select a new breed, because you will have to be continually importing rams, but if you have the same breed as your neighbor you can "swap" rams. This is the cheaper way. Our local supply of pure bred rams and ewes is being rapidly exhausted. If you have not already purchased, you had better book your order soon. Deal with reliable people and whenever possible made a personal selection.

HAY INSPECTION

According to legislation recently passed, at Ottawa, the following grades of hay will be recognized in the Maritime Provinces:

(a) Prime Timothy shall be pure timothy, perfect in colour, sound and well cured;

(b) No. 1 Timothy shall be timothy with not more than one-eighth of clover or other tame grasses mixed, of good colour, sound and well cured;

(c) No. 2 Timothy shall be timothy with not more than one-third of clover or other tame grasses mixed, of good colour, sund and well cured;

(d) No. 3 Timothy shall consist of at least fifty per cent. of timothy and the balance of clover or other tame grasses mixed, of fair colour, sound and well cured;

(e) No. 1 Clover shall be clover with not more than one-quarter of timothy or other tame grasses mixed, of good colour and well cured;

(f) No. 2 Clover shall be clover with not more than one-suarter of timothy or other tame grasses mixed, of fair colour, sound and well cured;

(g) Mixed Hay shall be hay which does not come under the description of timothy or clover, and which is in good condition, of good colour, sound and well cured;

(h) No Grade shall include all kinds of hay badly cured, stained or out of condition;

(i. Shipping Grade shall be hay in good condition, pressed, sound and well cured.

The No Grade or Rejected Hay are as follows:

(a) No Grade Hay shall include all hay that is damp or otherwise unfit for storage, and shall be entered in the Inspecting Officer's books as "No Grade", with a note as to its quality and condition.

(b) Rejected Hay shall consist of hay containing fox tail or spear grass, or hay heated or containing must or mould or otherwise damaged, and shall include all hay not good enough for other grades.

All inspecting officers shall where necessary enter in their books detailed reasons for grading every bale of hay.

The wire to be used in baling hay shall be number fourteen standard gauge annealed steel wire.

All Inspectors must take note of the condition of the fastenings of the bales, and all scales used for pressers must be inspected, at least, once every year.

A license fee of $1.00 will be charged every one who presses hay for sale or exportation. Such license can be had from the Minister of Trade and Commerce.

On every bale of hay sold a metal tag must be attached, having the license number of the presser, the weight of the bale and the month and year in which such bale was pressed.

All importers of hay in bales disposing of such in less than carload lots, must attach a tag on every bale, giving the name and address of the importer, and the weight of the bale.

All hay imported into Canada shall be inspected and graded according to recent legislation.

Where inspection is necessary, railway companies must where practicable, facilitate this work by placing the cars on sidings or where proper facilities are arranged.

Any person who presses hay for sale without securing the necessary license, shall be liable to a fine of twenty-five dollars for a first offence, and for each subsequent offense a fine of fifty dollars.

Any person who puts any foreign matter into any bale of hay intended for sale, which improperly increases its weight or prejudically affects the quality of the hay shall be liable to a fine of twenty-five dollars for a first offence, and for each subsequent offence to a fine of fifty dollars.

Any person who marks or stamps upon any tag attached to any bale of hay a wrong weight shall be liable to a fine of twenty-five dollars for a first offence, and for each subsequent offence to a fine of fifty dollars.

CAN YOUR HENS FOR WINTER USE

"Canned chicken" may be made at home in your own kitchen out of the old hens that ought to be killed anyway.

The method for operation for what is known as "Straight Pack" by the trade is very simple and is given in detail as follows by Dr. Robt. Barnes, Chief of the Meat and Canned Foods Division Health of Animals Branch, Department of Agriculture, Ottawa.

Clean and cut up the chicken.

Sort out the fleshy portions, such as the legs, thighs and breast.

Break off the protruding portions of the bones in each piece.

Pack these fleshy portions in a gem jar or other container, as closely as possible.

Add salt and pepper. (About a teaspoonful of salt and ⅛ teaspoonful of pepper.)

Fill to within ¾ inch of overflowing with the liquid that comes from the balance of the chicken, process for preparing which is given below.

Place in boiler or other vessel containing warm water and gradually bring to a boil.

For pint jars boil 2¼ hours.

For quart jars boil 3½ hours.

For the balance of the chicken.

Place in kettle and boil till the meat will strip free from the bones.

Strip off all meat and pack in jar.

Pour thereon the balance of the liquid in the kettle that has not been used in the first jar. If there is not enough liquid to fill the second jar, add water. Place in boiler as above, and boil as follows.

For pint jars 1¼ hours.

For quarts 2¼ hours.

If desired, the whole of the chicken may be prepared the same as the last part.

In all cases take care not to expose the gem jars to a sudden change of temperature. Also, after the jars have cooled off, examine the tops to see that the covers are air-tight.

During the cooking of the product, place the glass tops on the sealers but do not fasten them. Any steam or gas which may be generated will escape. As soon, however, as the process is finished, fasten the tops securely.

While describing the method of canning, something should be said about the poultry to be canned.

What is preferred are good, plump fowls, with a fair proportion of chickens, the bones of the latter giving a firmer jelly and lessening the danger of a soupy or slushy product. As a precaution against this condition, where the pack is straight fowl, gelatine may be, and often is used.

So much has been said and written about the prouer methods of starving, bleeding and plucking poultry for market that is is useless to go over them again. One can only emphasize the necessity of exactness in carrying out the accepted principles in connection with these points, which are just as applicable to poultry to be canned as they are to those intended for the market.

There is another point which is important, although possibly its carrying out may detract from the appearance and affect the sale to an inexperienced buyer, namely, that all poultry intended for food, canned or otherwise, after being properly starved, bled and plucked, should be left undrawn and kept in a suitable temperature for a day or two in order that the chemical changes which follow the killing of the bird may have an opportunity to take place.

CO-OPERATIVE BUYING

Editor Farmer:

The question as to whether or not it pays the farmer (producing milk at factory prices), to purchase mill feeds, has always been a lively matter of debate, particularly since feeds have advanced so much in price.

To my mind this will always depend on the proportionate price of feeds, to milk and the kinds or cows fed, and the skill of the feeder, but in a province where the soil is light and on farms where fertilizers are purchased, I think it will always pay the farmer to use considerable quantity of concentrates. If one ton of oil cake and cotton seed meal fed on the farm is worth eighteen or twenty dollars, (as analysts of note claim it is), and mill feeds of more than half that richness, then if we have been in the habit of purchasing commercial fertilizers and find they pay, why would it not be good business to buy mill feeds even if we only made the extra cost of them out of the milk. In fact, I cannot see why it would not pay us to use this feed, even if we did not always get the full cost in return in the extra flow of milk. If we lost $100 feeding meal for the sake of the fertility gained, we would be no worse off than if we purchased $100 worth of commercial fertilizers. In either case we would spent $100 for manure.

However, I don't think it is necessary to lose money feeding meal, as any good fresh cow will pay a fair margin of profit even at present prices, and young growing stock of all kinds, particularly hogs, can be given considerable, if carefully fed.

Four lbs. clean grain will make one lb. of pork if fed in conjunction with a little milk, and hogs worth fifteen cents on the hoof will make more rapid and cheaper gain if given a little middlings and oil meal with either skim milk or whey, on a grass run or fed some other green feed.

It is never economical for farmers who have considerable milk or whey to do with little or no grain. All experiments have gone to prove that the smaller the quantity of milk fed a growing hog down to 8 or 10 lbs. a day, the more valuable the milk proved, and even at present prices of mill feed, no farmer can afford to depend altogether on milk and grass for his hogs. However, I am not in this article going to discuss the question so much as to whether it pays to use meal, as to how the feeders should aim to buy it. This is the important point. Mill feeds are subject to as many variations in price as any other food product, and the question of its profitable use depends largely on the method of purchase, and I was pleased to note some time ago, that the Maritime Farmer was offering to assist dairymen in their purchase. Also to learn recently that they were taking the matter up with any creameries or other farmers' organizations, and at once placed my order with our creamery.

This is the first real co-operative buying we have attempted, and I trust dairymen all over the provinces will take a hold of the matter. Large orders mean low prices, and when any concern in touch with the millers is offering to do this work for practically nothing, the very least we should do is to give them a chance to do our buying for us. Last year most of us paid from fifty to one hundred per cent. more for mill feeds than we might, had we bought earlier. This year mill feeds may not go any lower, but in any event we stand to gain by placing our order as early as possible. The objection that some make against ordering any quantity, unless prices are first quoted, is unreasonable, as it would be impossible for any Company to have time to send offers to each individual or organization and wait for a reply, before replying to an offer, as very often the time is too limited and we have to take a little risk at any rate. But the chances of our getting feed at the best price from a business concern that could give very large orders at net price, seems to be to be much better than for each buyer to fish for himself. The wholesale and retail dealers are not working for advertising purposes, and will follow the market quite as rapidly as it advances. It is the greatest folly to be buying in little drib drabs and paying so much more for it every year. Most of us are short towards spring and have cause to regret not making wiser provision. So let us anicipate our real needs and give the Farmer an opportunity to do business for us.

A. W. LEA.

DAIRY FARMING OFFERS GREATEST RETURNS POSSIBLE

At the present time there seems to be a tendency on the part of some to boost the beef-raising industry at the expense of dairying. While it would not be wise nor just to do or say anything against the interests of the former, it would be equally wrong and opposed to the welfare of the public at large to underestimate the importance of the latter. Both of these industries are useful and each should work out its own destiny without interference or harsh criticism on the part of the other. If on the one hand there are localities where the beef breeds have always been the favorite and the residents have been able to make good in this branch of their farming operations, it is equally true, on the other hand that the dairy cow has demonstrated the fact that in other localities she is able to out-class all other farm animals as a profitable investment for the progressixe farmer.

It is now about fifty years since this industry took on a co-operative aspect, and down through the intervening years since that time, it has made steady and satisfactory progress until to-day the value of the milch cow, according to statistics from Bureau of Industries, is greater than that of all other cattle combined.

This business was introduced at a time when there was great need of an extension of the animal industry. Farmers who had depended on grain growing and selling the product in its raw state, soon began to find that the yields of their fields was steadily decreasing year after year, the outlook for continued profitable agricultural conditions was not encouraging, and no solution of the problem was in sight. At this juncture Harvey Farrington, the pioneer of the co-operative system of handling milk and the cheese factory system in Canada erected a factory near the vollage of Norwich in Oxford County. The formers in this vicinity soon found that they could keep ten or fifteen cows on one hundred acres of land and still grow as much grain for market as before; with the result that dairying was soon hailed as the salvation of the farming business in that section. The success attending the efforts of these pioneers was soon heralded abroad and other sections joined the ranks also. About this time the Dairymen's Association of Western Ontario was organized and largely as a result of its influence better methods of manufacture were adopted and a more uniform article for the export trade which had rapidly been secured, was produced. From this small beginning it spread over the province and the east and has become one of the leading industries of the country. Still later on in the history of dairying, butter making was taken up. The factories had been lying idle through the winter and this product was a burden on the farm home. Hence the co-operative principle was adopted in connection with this article also. Winter dairying was encouraged and as a result the milking herd has been a source of revenue all the year round. Still later the milk condenseries have been introduced and in some sections have reached enormous proportions.

Towns and cities having multiplied in numbers and population, a great demand for dairy products has arisen in them, and to-day the home consumption is a very large factor as an outlet for this class of goods. Good wholesome milk is an absolute necessity for the growth and development of the child, and even for the adult might well form a part of the daily ration as perhaps no other article on the market can compare with it as an economical food. Not only has this industry grown and reached large dimentions, but with the aid of the organization already mentioned, its conventions and the support of the government, it is to-day splendidly organized for the protection of its interests and the prosecution of its activities.

Would it not therefore, be the height of folly then after having taken half a century to bring this industry to the unique position it occupies to-day, both in the home and foreign markets to allow it to decline, and sacrifice it for other interests that have not been able to keep pace with it in the past and none of which have any brighter outlook for the future. It has never been shown to be good business policy for one to be continually changing from one business to another nor from one phase of business to another in the same line, unless some great outstanding feature likely to be permanent rendered the one unprofitable and increased the other. As a rule it takes a man many years to attain proficiency in any branch of good business, and hence it should not be lightly thrown over for something else not so well understood. In this business of farming then in which no man that has ever lived has yet been able to learn all there is to know about any phase of it, he should surely consider the problem very fully, after having spent a number of years in any line, before making a change.

In no branch of farming is the opportunity for careful study greater than in the dairy business. If therefore one has been successful in securing a fair share of information with insight and ability to prosecute his business successfully the chances are largely against him improving his position by changing to some other branch of the industry or another occupation.

Considering the situation of the animal industry as we find it to-day, what would be the probable result if any considerable proportion of the dairymen because of the scarcity of labor or the high prices of other products should drop this branch and engage in the production of beef? It would most surely cause a great disturbance amongst cheese and butter factories. Many factories no doubt would find it unprofitable to continue their operations, would close their plants and the patrons that would have remained in the business would be forced into raising beef with the result of an over supply of the latter and a scarcity of milk products. The market that is fairly well balaced at the present time would be altogether onesided. The prcies in the one case would naturally soar while in the other they would be reduced below cost of production. But many will declare, as they have done under similar market conditions in the past, that there is no danger of overproduction. The experience of the past, however, has gone to show that the world's supply can very quickly fill a deficient market; the prices are particularly attractive and that under abnormal conditions there is danger of overproduction.

All classes of producers of live stock products are receiving remunerative prices at the present time and the circumstances should be exceptional indeed that would induce any to change.—O. V. Journal.

RULES GOVERNING WOMEN'S INSTITUTE CANNING COMPETITION TO BE HELD AT MONCTON, OCTOBER 2-3-4, 1917.

1. That only members having paid fees for current year contribute jars to the Institute exhibit.

2. That no more or no less than twelve jars be included in the exhibit, and no two jars must be alike.

3. That at least five of the fruits, five of the vegetables, and two of the meats be selected from the following:

Fruits—Strawberries, Raspberries, Pears, Plums, Peaches, Cherries, Blueberries, Currants, Rhubarb, Quinces, Grapes, Apples, Crabapples, Blackberries.

Vegetables—Beans, Peas, Corn, Tomatoes, Spinach, Mushrooms, Beet tops, Beets, Dandelion Greens, Carrots, Fiddleheads, Asparagus, Swiss Chard, Pumpkin, Parsnips.

Meats—Salmon, Poultry, Beef, Pork, Game.

4. That only pint jars with glass tops and wire clamps be used.

5. That each jar be labelled with a gummed label provided by the Department free, with the name of contents, name of Institute and date of canning neatly printed thereon, this label to be placed on face of the jar at the bottom.

6. That the Institute pay Express charges to Moncton and if the Department cannot arrange with the railway to give free return transportation, the Institute will pay for same.

7. That each exhibit be carefully packed and the list of contents with name and address of shipper (Institute secretary, etc.,) enclosed with exhibit.

8. That if the jars are to be sold and the money forwarded to the Institute, the memo of contents enclosed in exhibit will say so, or if jars are to be returned, this memo will indicate such.

9. That each Institute notify the Supervisor as to entering the Competition not later than August 31st, after which date each branch will be informed as to the number competing.

10. That all exhibits to be sent by EXPRESS, (when possible), to the Supervisor, Moncton, N. B., not later than September 27th.

PRIZES WILL BE AWARDED ON THE FOLLOWING BASIS:

If from	1st prize	2nd prize	3rd prize	4th prize	5th prize	6th prize
85 to 90 Inst.	$22.00	$21.00	$20.00	$19.00	$18.00	$17.00
80 to 85 "	21.00	20.00	19.00	18.00	17.00	16.00
75 to 80 "	20.00	19.00	18.00	17.00	16.00	15.00
70 to 75 "	19.00	18.00	17.00	16.00	15.00	14.00
65 to 70 "	18.00	17.00	16.00	15.00	14.00	13.00
60 to 65 "	17.00	16.00	15.00	14.00	13.00	12.00
55 to 60 "	16.00	15.00	14.00	13.00	12.00	11.00
50 to 55 "	15.00	14.00	13.00	12.00	11.00	10.00
45 to 50 "	14.00	13.00	12.00	11.00	10.00	9.00
40 to 45 "	13.00	12.00	11.00	10.00	9.00	8.00
35 to 40 "	12.00	11.00	10.00	9.00	8.00	7.00
30 to 35 "	11.00	10.00	9.00	8.00	7.00	6.00
25 to 30 "	10.00	9.00	8.00	7.00	6.00	5.00

The list of prizes is extended to 18th place in case 85 to 90 institutes compete. Each prize being $1.00 less than the preceeding prize, the 18th prize being $5.00. In the other combinations the same graduations are worked out, $5.00 being the lowest prize in every case.

N.B.—If less than TWENTY-FIVE Institutes compete, NO prizes will be awarded, but transportation charges will be paid both ways.

GOOD VENTILATION BRINGS HEALTH, WEALTH AND HAPPINESS TO FARM LIFE

The general term, ventilation, is one that covers several things: it includes not only the supply of an adequate amount of fresh air, but the removal of foul air as well; it means better sanitation, greater warmth, fewer germs—in short, increased efficiency all around. It means stock with bright eyes, sleek coats, good appetites; cows that give records in milk production; lusty, red-combed hens that cackle constantly; vigorous swine with heavy jowls; and with it all, it means more money in the farmer's pocket.

Experiments have been conducted at various places which indicate conclusively that ventilation is an essential requirement if conditions are to be maintained in such a way as result in maximum efficiency. Take, for example, the results of the work of one of our Experimental Stations along the lines of poultry house construction. In this project houses of different types yere used, some entirely closed, some open, and some with openings protected by curtains of cloth which served to eliminate drafts; the last type is popularly known as the "curtain front house. The experiments, extending over a period of years, proved that not only were the fowls sheltered in the curtain-front house healthier and more productive, but the succeeding generations possessed greater virility and stamina. These results are but a single instance where fresh air has been converted into definite form in dollars and cents.

There are a few fundamental facts and figures relating to the subject that perhaps should be briefly summarized here. Everyone knows that as air becomes warmer, it expands with a consequent lowering of its density, or weight per unit volume, and therefore rises; vice versa, air acquires a greater density and consequently descends when its temperature is reduced. With a knowledge of this condition of affairs, it is immediately evident that a circulation of air can be produced and maintained in a building if a portion of the air within it can be warmed and if some means be supplied for inlet and outlet.

Another question is that of humidity, one which is quite often lost sight of by the thoughtless. By humidity is meant the moisture content of the air; it is usually referred to as the relative humidity, the amount of moisture in the air being expressed as a percent of that contained in air completely saturated. At the same temperature, air with greater relative humidity is naturally heavier than that with low humidity. This has an important bearing on the ventilating proposition, for in the air exhaled by animals there is a considerable amount of moisture, and if this be retained within the building in which the animals are kept, the air may become so heavy and sluggish as to seriously impede circulation. Besides this, it produces an unhealthful condition, for while absolutely dry air is of course undesirable, too great humidity will be worse in that it is conducive to disease and to an actual lowering of resistance and vitality.

The amount of moisture eliminated through the lungs and skin of a 1,000-pound steer amounts to more than 10 pounds per day; in a dairy barn of 100 cows, this would then amount to 1,000 pounds, or 120 gallons, or 3.8 barrels of water, every twenty-four hours. This moisture must be removed by being absorbed and carried away by the air, since the relative humidity of external air is seldom less than 70 per cent. and since the rate of absorption grows less as the point of saturation approaches, it is very evident that a considerable quantity of air must pass through the barn in order that this result may be accomplished. Otherwise the moisture, instead of being removed, will be condensed upon the walls and ceiling.

To show the necessity of supplying a large quantity of air for this purpose, let us assume that we have a small dairy barn 36 feet wide, 40 feet long, with the ceiling 9 feet high, and that 20 cows are housed in this barn. The outside temperature is 30 degrees with a relative humidity of 70 per cent., and the temperature in the barn is 50 degrees. The 20 cows will exhale a total of about 210 pounds of moisture in 24 hours. Air in being warmed acquires an ability to take up moisture, and in this case, assuming the temperature rise to be from 30 degrees to 50 degrees and that the air upon leaving the barn is saturated, each cubic foot of air will absorb 0.00039 of a pound. To remove all the moisture, the enormous amount of 540,000 cubic feet of air must flow through the building, at the rate of 1,125 cubic feet per hour for each cow. As a matter of fact, more than this would be required, since the assumed relative humidity is lower than the average, and since the outflowing air would not be fully saturated so to increase this figure by 25 per cent. is not at all unreasonable.

Mechanical systems of ventilation are as yet practically unknown as applied to farm buildings. The principles that have previously been enunciated apply in the main to what may be called "natural automatic" systems, insofar as the principles themselves are simply natural principles, and these systems operate practically automatically, with little attention beyond a regulation of the air flow by means of valves or dampers. Valuable as the natural systems doubtlessly are, consideration must also be carefully given to the mechanical system, which by a power-driven vacuum or plenum fan forces air into a building under conditions that can be regularly and definitely controlled. True, there must be some source of power; electricity is often available; perhaps a small gas engine can be utilized; at any rate, only a very small amount of power is required, for under such conditions as affect a farm building, air can be moved very easily. With the mechanically operated system, entire independence of variable weather and more variable wind can be had.

In the natural system of ventilation the outlet flues are an important part. They may be constructed of wood or of galvanized metal, preferably the former on account of the smaller tendency to precipitate moisture out of the air; in any case, they should be airtight, well insulated, as straight as practicable, and should always be kept clear.

Inlet flues have to be adapted to the construction material used in the building. Their maximum cross-section area should not exceed half a [illegible] ber of them must be used. In a frame building, the intake can be located between the studs very handily. In concrete walls, wooden or metal forms can easily be set into the forms, so [illegible] Brick or stone walls can, of course, be readily laid up so as to contain [illegible] In all cases, the outer opening of the inlet [illegible] with coarse screen to keep out birds, and [illegible] the inner opening, to prevent the flue from acting as an outtake.

In conclusion it may be said that the farm animal is simply a farm

LEARN TO VALUE TIME

A writer in an exchange says: "I was very much interested a few days ago in observing two men, each of whom were hitching a horse to a buggy. They began at the same time and each seemed to work just as fast as the other, yet one was through several minutes ahead of the other. My curiosity was aroused and I looked over the two methods of hitching up. The one had snaps to fasten the reins to the bridle; the other had to buckle his. The one had his hold-backs already attached to the shafts with a snap to hook into the breeching; the other had them attached to the breeching and at each hitching-up had to wrap them about the shafts several times and then buckle them. The one had patent metal holders on the ends of the single-tree to hold the tugs on; the other had the old kind, a little strip of pointed leather that must be drawn through a hold in the single-tree.

This set me to thinking. For a hypothetical case, I assumed that each of these horses were hitched up and unhitched every day in the year except Sunday. At two and one-half minutes saved each time the one horse is hitched or unhitched, we have 1,500 minutes saved during the entire year. At 13 cents an hour for man power, this amounts to $3.25. At the most, 75 cents paid for extra equipment, the holders and snaps. Deducting this amount from $3.25 the one man is still $2.50 ahead of the other at the end of the year.

Good farm management consists in figuring on little things as well as the bigger things.

PROFIT AND LOSS IN FARM BUSINESS

The matter of bookkeeping on the farm is not a new topic. Ofttimes we hear an elderly man say, "I am not too old to learn." It is for a reason, perhaps, similar to this that we wish to bring it up again. We all know how we are sometimes skeptical when some new idea is advanced alone some line, which is said to be practical. It might be of great benefit to use, but we leave it for the other fellow to try out.

There are very few farmers who keep accurate accounts of costs and credits. Those who start this, very seldom discontinue the system. They have found that to make their business efficient they must have a complete and properly arranged cost statement to enable them to study and to compare methods, and finally to determine by what method they can produce a certain article the cheapest. One of these articles, the production of which must be kept as low as possible, is milk. Especially is this so right now, when the prices of feeds are so high. By keeping books, a farmer will find out what it costs him to produce milk, and he will, as a result, keep a closer watch on the prices of different feeds. He will find out whether his dairy as a whole is profitable. He will find out whether it is profitable to raise his heifer calves or whether he should dispose of them.

We could go into detail and point out many other reasons why we should know what we are doing. A city concern must know how it can keep down expenses. The books show the management how this can be done. In like manner, we must consider our farms as factories, and if we wish to make the largest returns possible from our factories, we must have some way of checking up. It will be a simple and easy task if we use system.

CHOKE OFF THE WEEDS

A weed is a wild plant bred and trained to struggle and fight for its existence. A cultivated plant has had much of the fight taken out of it through long years of selecting and training it for useful ends. Nothing can remain a wild fighter and at the same time excel in useful qualities. One quality must give way as the other advances. The original dog and wolf were probably much alike in character. The modern house dog, dwarfed in size and trained in gentle habits, must be protected from the wolf, or the latter would eat him up. In like manner, corn or wheat or potatoes or root crops can never hold their own against quack grass, ragweed or other noxious weeds. Left to themselves in such a struggle the useful or "cultivated" plants are always swamped. The cultivated grasses, in a sour, neglected lawn or pasture give way to the weeds and poor grass, but put on limei and nitrogen and phosphorus and the better grasses come back and occupy the land. This same thing runs all through life, for as plants or animals are improved and made more useful through selection and care they must have higher culture, better feeding and more careful protection. They are no longer fighters, but things to be defended and fought for as the price of their improvement.

DARK DAMP STABLES DEPRESS THE COW

One of the most important features of the dairy barn is good ventilation. A cow stable that is damp and dark is a breeder of disease and discomfort. If the walls of the barn gather moisture or are thickly covered with frost it is apparent that the ventilation is unsatisfactory. Livestock can stand a considerable amount of cold, dry air but just as soon as called upon to breathe damp, foul, moisture laden atmosphere they become more susceptible to disease germs and they are unable to make the best use of their feed.

There is nothing that offers a happier home for the forms of bacteria that breed disease than dark, clammy stables. Sunshine is the greatest enemy of germ life and it is one of the cheapest purifiers available. Next to this, or in conjunction with this is some system that carries off the heavy laden air that has been used until it has lost its invigorating element.

Just at this time much is being said about tuberculosis and other germ-borne diseases. These diseases should be fought in every possible manner. We believe in the "accredited herd," but we believe it is equally important that we have "accredited barns" before we have "accredited herds." We believe it is of the utmost importance that everything be done that can possibly be done to control this disease which is such a vital one in connection with the cattle industry. We do not believe in any scarce heads or radical action, but we do believe in cleaning up and straightening out the breeding industry from this standpoint. Begin by giving the cattle clean, bright, well-ventilated winter quarters.

VEGETABLE SEED GROWING

The present outlook upon the seed situation for supplies of garden vegetable and root seeds, demands that local growers attempt to produce such seeds locally, at least in sufficient quantities to meet local demands.

What amounts to a virtual prohibition of exports of such seed, is now in force in Great Britain through the Censor's Office, and with the inauguration of a greater production campaign in the United States, the outlook for Canada is "scarcity". If gardeners and farmers are warned in time, a great deal of such seed could be saved at home from gardens and fields.

There are now approximately approaching one hundred acres of turnips ground, sown during late summer, for the production of turnips from which to produce a seed supply for next year, for the spring trade of 1919. But other seeds too will be scarce and N. B. farmer's and gardeners should try to make provision as far as possible for such an emergency.

GOVERNMENT WAR CERTIFICATES ARE SPLENDID INVESTMENT

Every bank and every money order post office in the Dominion offers an opportunity for national service. They are the agents of the Government which is appealing for public investment in War Saving Certificates. Such certificates are on sale at the banks and post offices. They bear interest at the rate of over five per cent. They are issued in three amounts for three year periods and are redeemable with interest at any time. By investing in them you are lending your money to your country and serving yourself. The return is excellent. The certificates are registered at Ottawa and cannot be lost. You lend your savings to the nation to be utilized for national purposes and you help directly in the financial mobilization of the country, which is essential to victory. Twenty-one dollars and fifty cents will buy you a certificate worth $25 in three years. Save your dollars and help to win the war. The soldiers are fighting for you. What are you doing for them?

* * *

School children should be taught fire prevention.

* * *

Fight the fly with cleanliness, tidiness and ventilation.

A WELL PLANNED BARN AT CHORE TIME RELIEVES FARMER OF ANNOYING WORRIES

The first step toward introducing efficiency methods in the management of the dairy farm is arranging the buildings, yards, fields and pastures so as to avoid lost motion and unnecessary hauling. Some farms present greater difficulties than others, owing to the size and shape of the fields and the general lay of the land. Other conditions being favorable, it is always best to locate the buildings and cattle yards so that the business can be most economically and efficiently conducted. Providing the water supply, drainage aspect, protection and general outlook is favorable, the dairy barn and cattle yards should be located as near as possible to the geographical center of the farm, and in close proximity to a public road. The main factors to consider are the saving of labor in handling the dairy herd and in coming and going from the buildings to various parts of the farm, or between the buildings and stores, markets and shipping station.

Clean, dry yards, protect on the sides exposed to prevailing winds and storms, are the first essential of cleanliness and comfort. If the barn and sheds are built on low, wet ground, and the cows have to wade through a mudhole when going out and in, it is almost beyond the power of milkers to keep foul bacteria and sediment out of milk. The foul mud dries quickly and readily falls into the milk pail. It is one of the most objectionable forms of dirt because it quickly finds its way thru the strainers and settles in the bottom of the cans and bottles. Cows that are plastered with this kind of filth should have their belly, flank, udder and teats thoroughly washed before being milked. If the location prohibits locating the buildings and yards on well-drained land it will pay to fill in the low places with gravel or cinders.

Clean and well drained cattle yards are one of the important factors in increasing the efficiency of the labor force. If the cows are kept in muddy, filthy yards they are unpleasant animals to handle at milking time. If there is anything that will disgust a hired hand more than sitting down to a cow that has her belly, udder and teats covered with mud and manure, it is to have the cow in the next stall give him a vigorous wallop across the cheek with a tail that has been dragged through mud and filth in the yards. Is it any wonder that so many self-respecting hired men refuse to work on dairy farms where such conditions prevail?

The yards should be arranged so as to facilitate handling the herd easily and without danger of injuring the animals. By having the yards subdivided one can turn out two lots of cattle without having to mix them up and separate them again. The dry cows and the young animals may go in and out without annoying the milking herd or injuring themselves. Little things these are, but some lives seem to be made up of little things, little bothers and aggravations like the ones avoided on a well-planned farm. Chore time can take on a very annoying length, not because speed is lacking, but because efficiency is not there. Efficiency means making a given amount of time and effort go farther and accomplish more.

Security of crops and stock is well assured by tight stretched woven wire fences and substantial farm gates. Old hedges, barb wire and rail fences should be removed and replaced with woven wire with a barb wire on top. Small, insecurely fastened end posts and slack wires have been responsible for many lost teats and injured udders. With substantial woven wire fences there is less chance for the stock to be injured by the fence or by getting into growing crops. Large, substantial end-posts set four or five feet in the ground and well braced, keep a fence permanently tight. Concrete anchor posts give excellent service and may be moulded right in place. The main consideration in buying woven wire fencing is the size of the wires. Nothing smaller than No. 9 wire should be used for dairy cattle. It requires just as much labor and just as many posts for the erection of fence from smaller wire, and the heavier wire stands up better and lasts for a much longer time. Good gates save time, risk and annoyance. One should have the gates so arranged that the yards and pastures may be subdivided as occasion requires. Anyone who undertakes to handle a commercial dairy can save money, time and labor by planning carefully the location and designs of the fences and gates. An efficient setting can be secured without extra cost. There is a great difference in the amount of labor required to handle a dairy on farms where these matters have been given thoughtful consideration. Good sanitary stabling is an essential part of success in handling the commercial dairy. Elaborate and costly buildings are not necessary to produce clean milk. On many farms there has been a tremendous waste of perfectly good money in buildings and equepment that are far too costly for the uses to which they can be put. It should not be hald up against the dairy business that it does not pay because some men with more dollars than sense have indulged themselves in working out half-baked theories about model dairy plants and dairy equipment, which have subsequently not made proper returns upon the investments. Dairy barns must be built and equipments added from time to time as the needs of the business indicate, and not built off-hand to satisfy a senseless whim. Every unnecessary expenditure becomes a charge against the business and prevents profits accumulating.

Modern efficiency is rapidly evolving a standard type of barn and stable. This barn is about thirty-six feet wide and as long as may be necessary to accommodate the number of cattle kept on the farm. This provides for two rows of cattle and gives the owner an opportunity to regulate the inside furnishings properly and to install feed and manure carriers, and to use milking machines. The manufacturers of the inside furnishings for dairy stables have standardized their stalls, stanchions and mangers to conform to these measurements. In building a new barn or remodeling an old barn it is always better to consult an expert and have definite plans to follow while the work is being done. So many excellent plans are available that it is hardly worth while to give advice concerning the inside measurements and choice of equipment. A visit to some well arranged dairy barn and a study of the methods of handling the herd will give one a better idea of the inside furnishings that can be had by reading a short article.

Concrete floors, feeding alleys and standing platforms come the nearest to meeting the sanitary requirements and permit the light to reach all parts of the stable. The side wall and ceiling should be smooth to prevent dust and dirt from gathering and dropping into the milk utensils and onto the cows. While the efficient dairy cow is the basis of efficient dairy farming, she cannot do her best work unless she is placed amid comfortable and sanitary surroundings. Good, comfortable stables, properly ventilated and lighted, are essential to heavy production and healthy cattle.

The location of the milk room so as to save time, energy and money is an important item in increasing the efficiency of the labor force. The same thing applies to the various details of feeding, cleaning and bedding the cattle. The dairy farmer who studies the problem of efficient herd handling will find it possible to effect a big saving in labor charges during the year, and derive more pleasure and satisfaction from his work than the thoughtless worker.

Clean and sanitary quarters for the calves and young stock are necessary to secure their proper growth and development. A good calf pen must have certain features. It must be dry, have proper air circulation, without drafts and not too cold. The pens should be bright and sunny. The direct rays of the sun should reach all parts of the floor some time during a winter's day because sunshine is one of the greatest purifiers. Dark mangers and corners should be done away with when building calf pens. They get damp and foul and become breeding places for disease germs and insect pests. Absolute cleanliness must be preserved in all parts of the pens especially the floors. As a rule it is better to have the calves and young heifers away from the older cattle. It reduces the risk fro mdisease and injury and facilitates the work of feeding and caring for them. The calf barn need not be expensive: if comfortable, well lighted and properly ventilated it will fulfill the requirements.

MILKING MACHINES THAT SAVE LABOR AND ARE EASY TO WORK AND CLEAN

That during the present labor shortage the milking machine may prove to be of great service on farms where twenty or more cows are kept, is a statement made in a recent circular from the New York experiment station. Directions for selecting, operating and cleaning the machines are given.

The same business judgment should be used in selecting a milking machine as would be the case in buying any other kind of machinery. The longer a machine has been in successful operation, the surer the owner can be that it is a mechanical success. A record of three years of successful operation is none too long to make sure that a machine is worth buying, the record having been made independently of the manufacturer.

As a general rule, the simpler the construction of a machine, the more likely it is to be a success. This statement applies especially to the teat cups. If they are of complicated construction it is very difficult to keep them bacteriologically clean. Statements made that machines, which allow stable air to pass into them with the milk, are failures because they are insanitary should not be accepted as the truth. Recent tests show that not more than one or two bacteria per cubic centimeter are added to the milk in that way.

Even though a machine which is as good as there is to be had, has been installed, it will not be a success upon any farm unless it is operated properly. It is as necessary to use judgment and care in milking a cow by machine as by hand. The cow is not a machine and never can be made over into one. If you fail to make a success of a machine which others have successfully used for several years, the pr babilities are that the trouble lies with you. Instead of getting discouraged, study the machine and try to discover what is wrong.

Keeping the machine clean is just as important as operating it properly. Very few farmers using milking machines keep them bacteriologically clean. Where this is not done the milk usually has a germ content of 50 to 10,000 per cubic centimeter as it enters the teat cups and leaves them with a germ content of 200,000 to 5,000,000 per cubic centimeter. Such milk sours very quickly and is not fit to be sold as market milk, or for butter or cheese-making.

The pail can be kept clean in the same way that any milk pail is kept clean, that is to steam or scald it and dry it out thoroughly. The rubber parts can not be cleaned in this way but should be kept in a disinfectant solution. Various germicides have been tried out for the purpose and several of them are valid, but the one which has proved the most useful in the experience [illegible] is formaldehyde. [illegible] is prepared as a 40 per cent. [illegible] is good or poor [illegible] the price.

When purchasing [illegible] do not buy more than one or two 12-ounce cans at a time and do not accept any in broken or rusted packages or any that is moist. If fresh, it should be a dry powder and of good strength. Prepare a stock solution by adding all the powder in one can to a gallon of water in a pitcher or tall glass jar. This will give a greenish colored liquid with a heavy white sediment or lime.

Fill a second crock, holding 20 or 30 gallons with water and add one pint of the stock solution to this twice a week. Double the quantity will do no harm. The solution in the big crock loses strength quickly on using and in a few days will become useless if the new chloride is not added. It is advisable to add enough salt to the crock to make a strong brine as this keeps the solution from freezing in cold weather, and brine is of itself, a good solution in which to keep the teat cups. The salt, however, is not necessary if attention is given to keeping up the strength of the chloride solution. This solution may be used indefinitely, if its strength is maintained by adding fresh chloride of lime solution as directed.

Immediately after each milking prepare three pails. Fill pail 1 with clean, cold water, pail 2 with hot sal soda water, and pail 3 with clean, hot water. While the teat cups are still attached to the machine immerse them in these pails successively, at the same time sucking the water through them. Then take the teat cups and stanchion hose and either suspend them or immerse them in the solution in the large crock. Care should be taken when putting the tubes into the solution to make sure that all air bubbles are out of the tubes and that they are completely immersed.

Neither rubber nor properly-made metal parts are injured by the solution recommended. If trouble from corrosion of the metal parts occurs, it will show that the manufacturer of the machine has given little attention to making the machine sanitary or a mechanical success. Machines handled as above outlined, will be found to be as near sterile as it is practicable to make them. Milk drawn through machines cared for in this way is cleaner and freer from bacteria than hand-drawn milk. Once a week the rubber teat cups should be taken completely apart and each part thoroughly cleaned. No disinfecting solution will take the place of cleaning.

Just before beginning to milk, a pail of clear water, either hot or cold, should be sucked through the teat cups, in order to prevent traces of the disinfectant being carried over into the milk. Even if this does happen and traces are carried over, harmless compounds are formed like some already present in the milk. The action is such that it would be necessary to add large quantities of the disinfectant if anyone should attempt to use it fraudulently as a preservative to milk. If this is done, the milk has such an unpleasant odor and taste that it is unsalable.

On account of the labor shortage [illegible] market more with the intention to sell than to give satisfaction, therefore farmers should deal only with responsible [illegible] is worth more to them than the few [illegible] by [illegible]

HORTICULTURE

CODLING MOTH TRAP

A codling moth trap has been devised by E. H. Siegler, of the Bureau of Entomology, United States Department of Agriculture, to be used as a substitute for what is known as the "banding" method for destroying the codling moth. The banding method, in which a folded strip of burlap is wrapped around the tree trunk, demands a considerable amount of labor, and the new trap is designed to minimize this.

The trap affords an attractive place for the larvae to spin their cocoons, and it prevents the escape of the moth after they emerge from these. The trap, which consists of a burlap band covered by a strip of wire screen, is made as follows:

Strips of burlap 6 inches wide are folded into three thicknesses. The loose bark from the lower branches and trunk of the tree is removed and a strip of this burlap folded once around the trunk. It is held in place by large tacks, which should be driven in in such a way that the edge projects about one-fourth of an inch beyond the burlap. The burlap is then covered by black-painted wire screen with 12 meshes to the inch. This is cut into strips 6 inches wide and the edges of each strip are folded twice, allowing one-fourth of an inch to each fold. The strip of screen should be long enough to allow for an overlap of 3 to 4 inches when placed around the trunk of the tree. The wire screen is placed over the burlap band and tacked to the tree in such a way that both the upper and lower edges fit snugly against the bark. The projecting tacks used to fasten the burlap to the tree prevent the wire pressing against the cloth. To make sure that no moths may escape through openings along the edges of the trap or along the flap, a thin coating of pitch tar may be used. This material, when heated, may be applied readily with a brush.

The traps may be placed on the tree at any time during the winter or in the spring not later than one month after the petals have dropped. As long as no openings occur in them they will require no further attention. The codling moth larva, having completed its feeding in the fruit, seeks a place to spin its cocoon, and for this purpose generally crawls up or down a tree trunk. Meeting the trap, it enters through one of the openings in the mesh of the wire screen and spins its cocoon beneath the burlap band. When it emerges as a moth its larger size makes it unable to escape through the opening in the screen by which it entered the trap.

It must be clearly understood, however, that this trap is not a substitute for spraying, but merely an additional precaution. Nevertheless, some larvae will invariably escape, and the offspring of these are largely responsible for the damage to the fruit crop. By the use of the codling moth trap, in addition to thorough spraying, the majority of the unpoisoned larvae may be captured and injury by later broods will be materially reduced.

DUST METHOD AND LIQUID SPRAYS.

Applying insecticides in the form of a dust is not by any means new. During the past twenty-odd years there have been numerous experiments in which the efficiency of insecticides and fungicides applied in the form of a dust were compared with the same materials applied in the form of a spray. Many entomologists, horticulturists and fruit growers have recognized the disadvantage of applying the poisons and insecticides as a spray, which necessitates the hauling of considerable quantities of water through the orchard. Ahe advantages which would be derived from the application of poisons in the dry form have always been a stimulus to these experiments. Until within the past two or three seasons, all comparative tests of the two methods have shown that the liquid sprays gave greater protection and that a greater percentage of the fruit was free from injury.

Within the past two or three years, however, the machines employed for dusting work have been very materially improved, likewise the materials used for dusting have also been developed so that without question the differences in effectiveness which exist between the two methods are not sa great as formerly.

Late Experiments

In New York, at the Cornell Station, an extensive series of experiments have been carried on for two seasons in which these methods were compared in a practical way; also during the same period similar experiments were being conducted at the Illinois Experiment Station. The results of these tests can not be gone into in detail, but it is sufficient to note that the dust method has given excellent results in preventing injury by codling moth and a fair degree of control of apple scab. The advantages that the dust method has over the older liquid spray are such that fruit growers should investigate this method. The dust machine itself is very light and thoroughly adapted to rough land. It is simple in operation and much less expensive than the ordinary power spraying outfit. The chief advantage, however, to be considered is the speed with which the dust can be applied to the trees. The application can be made very quickly, even from 30 to 40 acres in a single day being not unusual. Persons who have been accustomed to using liquid spray feel that the application of the dust is a very awkward operation and many are prejudiced against it.

As to the cost, there seems to be

The Transformation

Right in the heart of the great city of Toronto, in the centre of the principal business district, close by the cross-roads of main traffic, stands the "second longest bar" in all Canada. Observers say they used to count hordes of men entering this stronghold of the Traffic. Were the frequenters of the bar better men when they came out?

On September 16th, 1916, Prohibition went into force in Ontario, and, of course, the bar lost its license. On the 16th of April, 1917, the old bar was busier than ever! But what an arresting, beautiful transformation! Would that you and your sons could have been there to see the sight. The old barroom was a bevy of flowers. Fifty fair ladies served refreshments to Toronto's most prominent citizens and their wives, and not one of them all but was proud to be seen in the old barroom.

The aching, worrying hearts of the army's mothers are relieved now when they see their sons enter this building—for the old bar is helping to save men now instead of ruining them.

The hotel is now the "Y.M.C.A. Soldiers' Club," one of the Young Men's Christian Association's long chain of clubs, marquees, huts and "dug-outs" extending from Vancouver to the firing line in France—those helpful sentinel-posts that safeguard our precious soldier men and boys wherever soldiers are congregated. To the Y.M.C.A. Canada owes a debt of gratitude she never can adequately repay.

Like New Brunswick, the Traffic in Ontario has the opportunity, after the war, of putting Prohibition to the test at the polls. But Prohibition in Ontario is being *enforced*, and the old strongholds of the Traffic—the long bars we mean—are one by one being turned to useful purposes. Many of the hotel buildings that depended for existence upon bar trade are now devoted to commercial enterprises—constructive instead of destructive.

Does New Brunswick want to return to the destructive license system, and again be a partner in the old firm of John Barleycorn and Company, Limited?

Or does New Brunswick want to maintain Prohibition for ever? If so, Enforcement must be province wide, must be both strict and effective.

Help to Enforce Prohibition

Every man and woman in this province shares the responsibility for the proper enforcement of Prohibition—not the officers of the law alone. ***Your*** duty is clear.

Wear PALMER-McLELLAN'S Chromoil Tanned Farm Boot

THIS SUMMER
POST PAID TO YOU
$4.50
"The Boot with the Moccasin Comfort"

Here at last is the perfect combination of boot and moccasin. The general shape is that of a moccasin, but the boot is built on a last, with a long solid counter to hold up the heel. It has all the easy foot fitting comfort of a moccasin, and, at the same time, it will stand right up and keep its shape with any boot.

The new chromoil leather used is simply wonderful. The chromoil tanning process produces a through-and-through, instead of a surface, waterproof, and a leather much stronger and more durable than any other. These new farm boots will not crack and shrivel when dried by the fire. They remain pliable in weather that freezes other oil-tans. They outwear any other boot of their kind on the market, and give solid comfort and satisfaction every day.

If you have any trouble getting these new Palmer-McLellan Chromoil Tanned Farm boots locally, mail us the price and we will ship you a pair postpaid.

SUMMER SHOES FOR MEN WHO WORK

Here is something new in footwear specially suitable for farmers, woodsmen, millmen, trackmen, laborers—all those needing strong yet light, cool, easy shoes. These are made on good-fitting right and left lasts from our famous oil-tanned Skowhegan waterproof leather with waterproofed sole leather outsoles and solid insoles.

Palmer's "Moose Head Brand"
"SUMMER PACKS" and "HARVEST SHOES"

are light weight, comfortable, durable working shoes for spring, summer and fall wear. Sold by leading dealers everywhere. If your merchant does not carry them write us, giving his name and address, and we will see that they are placed within your reach. Made 4, 6 and 9 inches high. 19

JOHN PALMER COMPANY, LIMITED
Fredericton, N. B. - - Canada

very little difference in spraying or dusting for the codling moth. In applying the poison in the form of dust much greater quantities of material are used, but the increased cost of the poison is offset to a considerable extent by a saving of time and labor. Fruit growers who have had difficulty in controlling the codling moth and who have such a large acreage to spray that they are not able to get over the entire orchard within a few days after the petals fall, should investigate the dust method.—W. J. Schoene.

LEGAL REQUIREMENTS FOR FRUIT PACKAGES TO BE ENFORCED

At the request of some fruit growers and shippers, certain manufacturers have been induced to make fruit baskets which were not in accordance with the requirements of the Inspection and Sale Act, Part IX. This has created a condition which was unfair to the honest grower and shipper as well as to the consumer.

The sizes of the eleven and six quart baskets, the two most popular sizes used in eastern Canada, are specifically defined in inches. The eleven quart basket is required to be 5¾ inches deep perpendicularly, 18¾ inches in length and 8 inches in width at the top of the basket; the bottom shall measure 16¾ inches in length and 6⅞ inches in width. The six quart basket is required to be 4½ inches deep perpendicularly, 15⅜ inches in length and 7 inches in width at the top of the basket; the bottom shall measure 13½ inches in length and 5⅞ inches in width. All measurements to be inside the veneer proper and not to include the top band.

The packages which have been found in violation were made so as to contain less fruit than the standard although having the appearance of holding an equal quantity.

The Fruit Branch at Ottawa has endeavoured to secure compliance with the law by pointing out the advantages and desirability of uniform packages, but unfortunately it has not been able to obtain the desired result.

Instructions have been issued to the staff of fruit inspectors to enforce the Act in this regard and to recommend prosecution in every case of violation. The penalty provided is a fine of 25c for each package so found.

It is therefore necessary for growers and shippers to exercise great care in purchasing thei supply of fruit baskets to see that they are in accordance with the requirements of the law.

PREVENT WOOD DECAY

Especially in the stone fruits, wood decay causes great loss. A decayed tree may grow and bear fruit, but it soon shatters in a severe storm, or breaks under its load. Then there is the expense of planting another tree and waiting for it to come into bearing.

We recently read an account of fifty-year old peach trees still vigorous and bearing fruit. The claim was made that this was because the tree had been protected from wood decay. If we could gather crops for fifty years from the same peach trees it would seem worth while to keep them in good condition.

The decay is caused by fungi that enter some wound or unprotected spot—such as a portion over which the bark is dead and affords no shield from the fungi. Infection takes place only from spores that fall on dead bark or into the cracks of wounds. The resulting fungi grow in the wood, and, by a process of digestion, use it up and leave only ash.

The prevention consists of disinfecting any wound with a germicide, and, as soon as that is dry, painting over with some sealing paint. This should be done immediately, so that no cracks may form nor spores enter. No sealing paint can be counted on to last more than a year, and, therefore, the place should be repainted every season until the wound has completely healed over.

REMEDIES FOR CURRANT AND STRAWBERRY WORMS

The imported currant and gooseberry worm, or "saw-fly", has been introduced in several localities in Colorado and is very destructive to the leaves of these bushes. There are two broods a year, the first appearing quite early in the summer. If there is no fruit on the bushes, they may be sprayed with arsenate of lead, 1 pound of the powdered form, or 2 pounds of the paste form to each 50 gallons of water. When fruit is on the bushes, use white hellebore, which will kill the worms but will not harm people who eat the fruit. Apply the hellebore either by dusting lightly through a cheesecloth sack, or by putting 1 ounce in each 3 gallons of water and applying by means of a spray pump or a whisk broom. Apply promptly when the injuries are first noticed. Do not allow the worms to defoliate the bushes and ruin the fruit and perhaps kill the bushes as well.—C. P. Gillette.

Comfort in the Home

The Sunshine Furnace chases chills from coldest corners and insures utmost comfort in the home throughout the winter. Don't buy any furnace or heating plant until you have investigated the merits of the "Sunshine."

DAIRYING.

MORE MONEY IN DAIRYING IF FARMERS WILL ADOPT METHODS OF IMPROVEMENT

The desire to own better bred dairy cows and feed more liberal rations of rich concentrated feed stuffs has caused many dairy farmers to overlook other important factors that contribute to the success of the business. No matter how well-bred the cows, or how heavy rations they are fed, improper care for only a few days may change the result from gain to loss. The better the cows and the more liberal rations they are fed, the more important becomes the question of good care and skilful herd management.

The cow that is producing a heavy flow of milk and fed all the rich grain feed she can digest and assimilate is doing a large amount of work. Selective breeding and heavy grain feeding for an increased flow of milk have deveyoped an immense udder and a corresponding large digestive capacity. Nature did not create the cow to give milk for man. Man has simply taken her and developed her to meet his special needs. It is important that we take these things into consideration and give her care and surroundings that are in harmony with her new environment. Like any other animal that is developed for a special purpose she is stronger in some points and weaker in others; and the better the cow, the more delictae her organism and the more sensitive her nervous system, hence the more important becomes the question of good care.

Liberal Feeding Pays

Developing young heifers and getting them well started toward profitable reproduction calls for proper feeding and the best of care. If we are to secure evenly-balanced cows, we must feed the right kind of materials in sufficient amounts to develop the whole body as nature designed and not allow certain parts to develop at the expense of the others. Bred as our dairy heifers are, to produce milk in increased quantities, we must feed proper and generous rations so that they will be sufficiently developed to breed for their first calves when nature calls. Early breeding does not, other conditions being right, weaken the vitality of the heifer as many breeders and dairy farmers argue. All that it does do, is to make a demand for more food as two lives must be supported instead of one.

Use Well-Bred Sire

Having decided on breeding up the herd by selecting promising heifer calves from the best cows it becomes very important that the proper sire shall be used for breeding purposes and that strong and healthy calves shall be dropped. The sire should be a well-bred one. It is not enough that his name is recorded in a book and that he has a pedigree. The producing ability of his dams and grand dams should be known. Registration is of no particular value unless it stands for production. Cows are kept primarily for what they can produce at the pail, anl not simply to breed along fashionable lines or families of the breed.

Get a bull whose dam and grand dam on his sire's side were efficient producers. Never go back over three or four generations of registered scrubs to find some famous animal in the pedigree. Look for the desired excellence in the animal you are buying, or close up in the pedigree.

In order to obtain strong and healthy calves the cow should be well fed during pregnancy. The common practice of stopping all the grain ration when the cow goes dry is not a good one. The feed may be of the same nature as when she is milking, a good protein ration. The amount of grain feed may be regulated by the quality of the roughage and the flesh condition of the cow. Two or three weeks before it is time for calving lighten up the grain ration by substituting wheat bran for the heavier grain feeds. This stimulates the activitf of the digestive system and furnishes excellent material for building bone in the young calf.

After the calf is dropped it should have milk from its mother for the first few days. As soon as it becomes accustomed to drinking from a pail, eight to ten pounds of whole milk will be sufficient for the first three weeks. After that gradually substitute skim-milk and feed grain substitutes and fine, well cured hay. Whether one is to feed skim-milk and grain or prepared calf feeds, it is necessary to feed whole milk until the digestive organs become sufficiently developed to make good use of other feeds.

Heifers Should Pay for Selves in Five Years

Having reared good heifers given them good care up to the time they are five years old, they will have about paid for themselves. Some of them may not come up to the desired requirements, but most of them should if given proper care. They have paid us a fair market price for our feeds and left valuable fertilizing materials on our farms, enabling us to raise more and larger crops. These young cows are just at the prime of life and should be able to give good results for five or six years. In fact, some cows that are properly fed and given good care are frequently profitable until they are twelve or fifteen years old.

In these days of high-priced dairy cows and feed stuffs the question of good care becomes of still greater importance in getting at the profits from the dairy herd. Among the essentials of good care, comfortable housing and a supply of clean water are of first importance. This means that the cows should have warm, light and properly ventilate dstables, sufficient exercise to maintain bodily vigor, and an adequate supply of clean water to enable them to make efficient use of them rations. Such treatment is not merely humane: it is necessary. Regular feeding, watering and milking are es-

MOISE DEROSCE.

Hotel Keeper, St. Phillippe, Que.

sential to an even, well-sustained flow of milk. The best results are always obtained whereby the different work is done at the same time each day. Milking should be performed as quickly as possible without injuring the cow. It is very important that cows be milked clean at each milking, not only because the last of the milk is richest in fat, but because whatever milk is permitted to remain in the udder from one milking to another is not only lost, but acts as a check upon further secretion.

Sanitation Essential

In the production of sanitary milk and maintaining the health of the cows no one thing is of more importance than a clean, dry and comfortable yard. Too many dairy farmers do not fully appreciate the importance of keeping the surroundings sanitary, dry and free from manure and litter. Many valuable cows are seriously injured by going through mud holes and manure heaps in the yards, to say nothing of the inferior quality of the milk produced by cows that have their belly, udder, flanks and tail plastered with this barnyard filth. On most dairy farms a little grading, a few rods of tile drains and six inches of cinders over the surface will mean a dry, clean yard.

While the efficient dairy cow and an adequate supply of good feeding materials are chief requisites of successful dairying, they cannot return a profit under present conditions unless supported by good care and skillful management. Never in the history of the dairy industry has there been a time when attention to comfort, yard and stable sanitation and little details in herd management were so essential to profits.

Importance of Ventilation

Although necessary for the health of the cows, light and pure air are almost universally lacking in dairy barns. Windows and better system of ventilating are far cheaper than dairy cows and feed stuffs. Pure air is more important than pure water, just as pure water is more important than pure food. To make economical use of high-priced feeding materials and keep healthy and vigorous, the cows must have plenty of light, pure air and pure water.

Cows that are giving a full flow of milk require water in large puantities and at regular intervals. If water basins are not in the stalls, one should have a watering place in a sheltered yard and have the drinking tank so arranged that the temperature will be kept above 60 degrees Fahrenheit during the cold weather. Drinking cold water at irregular intervals and usually not in sufficient quantity results in a decided falling off in milk yields. It is very difficult to understand what process of reasoning will lead a dairy farmer to invest in high priced dairy cows and feed stuffs and neglect to provide such cheap and necessary essentials as light, air and pure water.—W. M. Kelly.

WEED THE HERD RATHER THAN TRY TO INCREASE IT

In forecasting events we are apt to be influenced too much by present conditions regardless of whether these are usual or abnormal. If a certain crop is a failure or a partial failure in a given year and prices are high it is fairly certain that the next year will see a large acreage planted and the market overstocked. If any line of meat product is low and live stock plentiful, the autumn is likely to see large numbers of breeding stock sacrificed and the following year meat scarce and high priced. The result of this practise is that when the prices are good farmers as a rule have little to sell and when they are low everybody has large offerings.

All classes are likely to get into that habit of unreasonably allowing present conditions to influence them instead of studying these in the light of future probabilities.

On account of the abnormal state of affairs existing at the present time it is even more difficult than usual to prognosticate regarding food values with any degree of certainty. It is well today, however, to look into the future, but even then no one knows what to expect. With some of the great leaders declaring that the war cannot last more than a year longer and others equally certain that it has only just begun leaves no ground of hope for the ordinary mortal to base his opinion of the future or its needs on any solid ground. Of one thing, however, all seem to agree, namely, that there is at present a great scarcity of food and that if the war continues for two or three years longer every available means will be needed to feed the Allies at home and abroad during the struggle.

It is a well known fact that cereals used as food will go a long way further in their natural state than they will when fed to pigs or cattle for furnishing meat to the public. With this fact before us it is not wise, under present conditions, to push the Live Stock interests in the way of increasing the size of herds. It will be much better to weed out all poor specimens and in this way increase their products without using as much grain as has been necessary in the past to produce a hundred weight of milk, cheese or meat. While this practise of curtailing the live stock industry might not appeal to some farmers, in the end there is little doubt that it would be a good thing. One of the greatest evils of this useful phase of farming has always been the keeping of a lot of inferior stock. All the milk and meat supply of the country could be produced with a third less cattle if first class stock only were kept instead of so many inferior animals.

A large saving of cereal food may also be accomplished by raising the legume fodder crops. A good cow will give a large quantity of milk on silage and good alfalfa or red clover hay in winter and good succulent pasture supplemented with silage and alfalfa in summer, and by providing these cheap foods in abundance cereal grain feeding may be reduced to a minimum. A large supply of sugar beets or mangels will also help out greatly in this respect. Let us therefore eliminate as far as possible cereal feeding to live stock by adopting these measures.

Of course these suggestions do not mean that stockmen should eliminate grain feeding altgoether from an animal's ration but rather that by the substitution of leguminous and succulent roughages the amount could be greatly reduced and only mill by-products be used as concentrates and these only in connection with heavy producing cows. In this way a great amount of cereal grain could be saved for human food, which is so badly needed at the present crisis of the world's needs.—O. V. J.

FEEDING DAIRY COWS

Fifty years ago the feeding of dairy cattle was a simple process. Feeds were home grown and few in number and there was little or no knowledge of feeding standards. Grain rations were often composed simply of corn, or oats or both, and cows were usually dry in winter.

By thoroughly understanding feeds, rations may be computed as occasion demands. The ration should be palatable, and as nearly like summer conditions as possible.

Breeders of wairy cattle will be interested to learn that Mr. C. S. Wood has been appointed chief inspector in connection with the Record of Performance work. Mr. Wood has been a member of the Federal Service since 1911, being assistant to the late Mr. D. Drummond.

GET YOUR
DE LAVAL
NOW

WHETHER you are selling cream or making butter, if you have no separator, or are using an inferior or half-worn-out machine, you are wasting cream, time and labor every day you delay the purchase of a De Laval.

You can't afford to wait another week. It means too much, now with butter at its present high price, and the importance of saving time and labor. Let the De Laval start saving cream for you right now, and it will soon pay for itself.

See the nearest De Laval agent right away and let him show you what the De Laval will save for you. If you do not know the De Laval agent, write direct for any desired information.

WOLFVILLE - - Nova Scotia.
Next Term opens Sept. 5th, 1917.

Alleged Profits of the William Davies Company in 1916 on Bacon, as Indicated by Department of Labor to be Five Cents per Pound, Untrue :

Actual Profits Two-Thirds of a Cent Per Pound

THE statement issued by the Department of Labor concerning the business of The William Davies Company Limited has been given widespread circulation throughout the country and provoked public unrest.

Whatever the technical wording of the report was, the effect has been that the newspapers have published that "the profits on Bacon alone" of this Company "for 1916" were about "five millions of dollars. This interpretation of the official report is not surprising in view of certain statements that the Commissioner of the Cost of Living makes. The commissioner is reported as saying that "There were two individual cases of profiteering in 1916 and that had these cases occurred since the passage of the cost of living Order-in-Council, he would consider it his duty to recommend that the facts be laid before the Attorney-General for consideration as to their criminality." The situation created by such erroneous and damaging statements is serious as emanating from a Government official, from whom one looks for not only accurate statements but correct conclusions.

The William Davies Company, being a private concern, has followed the practice of all private corporations, except when it made a bond issue in 1911, in that it has not published reports of its assets and liabilities or profit and loss. The present circumstance, however, in which a Government Official has led the public to false conclusions, makes it advisable for this Company, for both the public interest and its own interest, to publish particulars of its business as well as point out the error of the statement of the Government Official.

For the last fiscal year ending March 27th, 1917, The William Davies Company bought and killed 1,043,000 head of Live Stock (Cattle, Hogs and Sheep). This, plus purchases of outside Meats, produced 160,000,000 pounds of Meats. The Company handled 6,550,000 pounds of Butter and Cheese, 5,650,000 dozens of Eggs, and manufactured 26,500,000 tins of Canned Goods..

The net profits on these were .68 cents (or two-thirds of a cent) per pound on meats, 1.04 cents on Butter and Cheese, 1.04 cents per dozen on Eggs, and .47 cents (or slightly less than one-half a cent) per tin on Canned Goods. There profits include profits on all By-Products derived from these accounts.

During the year the Company served at its retail stores 7,500,000 customers, the average purchase of each customer was 35c, and the net profit on each sale was 5-8 of 1 cent.

The turnover of the Company from all its operations for the fiscal year ending March 27th, 1917, was $40,000,000. The net percentage of profit upon this turnover, after deducting war tax, was 1.69 per cent., or including war tax 3.45 per cent.

The William Davies Company has assets of $13,385,000, of which $3,865,000 is tied up in fixed investments.

To provide the necessary facilities for the increased volume of business the Company expended $750,000 in buildings and equipment during the year.

Companies of other character present no more reasonable statement of profit and loss based upon the investments made in the business.

The William Davies Company offered to the Imperial authorities, as well as to the War Office Service (which represents the Imperial authorities in Canada) to place the output of its Factory with respect to Bacon supplies, Canned Beef and Pork and Beans at the service of the authorities, on the basis of cost plus an agreed percentage. These offers were successively declined as the authorities evidently desired to purchase in the open market, and on this basis The William Davies Company has secured War Office business by open competition with the world.

Respecting the Report of the Commissioner on the Cost of Living :---

Last Winter the Commissioner, under authority of Order-in-Council, required packers to submit statements under oath for some years back and up to Decnmber 1st, 1916, of incoming stocks of Meats and the cost of such, as well as statements of outgoing products and the selling value. This Company represented in writing at the time that the information as specifically required was not in accordance with Packing House Accounting methods, and invited the Commissioner to send an Officer to the Head Office of the Company to examine the books for any information desired, and to secure a viewpoint as to the best way of collecting data which would be of use to the Government. This offer was declined, and there was nothing to do but fill in the information required as literally as we could determine it. For example, there was no recognition of the fact that a raw product may enfer a factory under a specific classification and leave the factory as a finished product under some other classification.

We submitted a series of accurate figures based upon our interpretation of the official repuirements which made no provision for charges of any description other than incoming freight and unloading charges to be included in the cost or to be deducted from the selling price. There was nothing in the report which could he read so as to determine a profit and loss statement. The very fact that with only a statement based upon cost of raw products and value of sales in Great Britain a Governmen: Official has deduced "Large margin," "Profiteering" and "Criminality" if it had occured since the passage of a recent Act, shows too dangerous a trifling and inc_pacity to be permitted to deal with any important situation. The statements of this Company have been treated by the author of this report as if the outgoing product was identical with the incoming product, and from the series of reports he has singled out two items—the Bacon and Egg reports—and from them deduced an erron-

(Continued on next page)

(Continued from preceding page)

eous "margin' which the newspapers have interpreted as "profit." The author of the inquiry shows a strauge lack of even a fundamental knowledge of simple bookkeeping and a dangerous inability to co-ordinate figures. The following are specific and outstanding errors in the report:

The principal item that is causing excitement deals with cold storage Bacon. The term "cold storage" is not defined, and the public is allowed to make its own definitions. As all Bacon in a packing house is under refrigeration it is really all cold storage, and therefore this Company's figures of cold storage Bacon represent the complete quantity of Bacon handled in its entire Plant, whether in freezers or in process of cure for immediate shipment. That some Companies interpreted cold storage product as "freezer" product only is evidenced by the smallness or entire lack of figures on the Bacon list for some Plants, indicating that many firms did not submit statements of their complete stocks, as did this Company. An official of this Company pointed out this cold storage distinction to Mr. O'Connor and Miss McKenna in Ottawa a few weeks ago, and the failure to make the distinc. tion after having had it pointed out evidences the lack of desire for accuracy of the real information desired.

It is true The William Davies Company, in 1916, exported 97,791,000 pounds of Bacon. but we do not know how the margin of 5.05 cents per pound is arrived at by Mr. O'Connor, as there were no figures to justify such a conclusion. The probabilities are that the margin is arrived at by taking the average cost per pound of incoming product from the average selling price per pound of outgoing product. This may be a rough way of estimating the gross margin when dealing with small figures, but when dealing with figures the size that Mr. O'Connor has to deal with, a very small fraction of a cent per pound of error makes a very important difference in the total, and one must be careful to make sure that the outgoing product is the same finished merchandise of the incoming product reported on.

Allowing it to pass, however as a rough estimate, we wish to point out (first) the inquiry of the Commissioner allowed only for incoming freight and unloading charges, and made no provision whatsoever for operating charges of any kind, such as labor, curing materials, refrigeration et cetera. Such actual charges on the 97,791,000 pounds exported were $1,162,000—or 1.2 cents per pound. This amount covered all charges up to the point of placing the Bacon on cars f.o.b. packing house. In addition to this was the actual cost to land and sell this 77,791,000 pounds in England after leaving the packing house, which involved charges of 2.9 cents per pound —$2,836,000. This 2.9 cents per pound included inland and ocean freight, landing charges, war and marine insurance, cables, and selling commissions to agents. The ocean freight and war risk alone would make up 2.4 cents of the charge of 2.9 cents per pound. This 1.2 cents, plus 2.9 cents—a total of 4.1 cents—must be deducted from Mr. O'Connor's margin of 5.05 cents per pound, leaviug a margin of .95 cents, or slightly less than a cent per pound, which still has to be reduced because of the error of premises and because of further factors which have to beconsidered to determine net profits.

It is puite evident some of the other pack ers did not show selling values in the country in which the goods were sold—a proceeding puite proper, as the forms submitted to be filled in were indefinite and ambiguous, thus permitting without charge of evasion a variety of interpretations as to the information required. It is thus possible that of all the figures submitted by the different packers that no two sets of costs and sales prices are determined at the same common point. It is this difference of interpretation of what was required that accounts for the difference of the alleged "margin" made by the different companies. Common conclusions, however, have been drawn by the author of the report from varying bases of premises.

The figures of the Egg business were sub-

(Second) The above margin of [illegible] pointed out that the author of the report charged out the Bacon figures at [illegible] the selling price [illegible] over cost, but he did not give us credit for the statements of other product, of which figures were submitted, [illegible] under cost. The reason of this was that through failure to inquire the Department [illegible] looked the fact that product [illegible] pork, and through the process of manufacture, go out as Bacon, or, in another instance, enter the factory as beef and go out in the form of canned meats; for example: much of the product which came in as pork, and which was entered on the pork sheet submitted to the Commissioner [illegible] and left the factory in the form of Bacon, and was therefore entered on the outgoing side of the Bacon sheet. [illegible] sales are increased by this amount over the incoming stocks of Bacon, and, likewise, the sheet showing the sales of pork is reduced by the amount that went out in the form of Bacon. If the Department takes one set of figures that show favorable to the company they should take another set of figures that show unfavorable, as the principle in either case is the same, and failt ure to do so looks as if the author of the repor was exercising more enthusiasm than sound judgment is his investigations.

(Third)—It is queried in the report, that "if the margin of 3.47 cents" alleged to have been made in 1915, "was satisfactory, why was it necessary to show increased margin in 1916?" Assuming again for the moment the soundness of the premises in asking such a question based on an erroneous 'margin" it will be found that the increased margin is chiefly absorbed in increased ocean freight rates and war risk insurance in 1916, of which apparently the author of the report was in ignorance.

The Company does not challenge either the legal or moral right of the Government to investigate business enterprises when public interest directs such an investigation should be made. If an investigation of the packing and meat business is ordered, the Company will place at the disposal of the Government not only the data it would be required to supply under Order-in-Council directing that inquiry be made, but will place the experience of its officers at the disposal of the investigating committee, if it is considered they can render any service which will be of value. The Company has not now—nor at any time during the fifty years of its operation—anything to conceal in method or practice of carrying on its business. It does, however, claim the right to conduct its export business without abusive comment from Government civil servants —especially when the conclusions drawn from the data asked for are improper and false.

One of Canada's chief export industries is the packing business. It is essential to the live stock industry, and along with other export industries, it maintains the financial stability of this country and should, providing it is on a sound basis, receive encouragement and not slanderous abuse. In view of the publicity given to the report of the Commissioner on the cost of living, the Company demands the same publicity in having an official Government investigation of this report to determine the truthfulness or untruthfulness of its conclusions. We do not seek public consideration as a company, but we do say that untruthful official statements, or statements the effect of which is to create an untruth, adversely affect the live stock industry of this country, which is so valuable and essential a wealth-producing power and, in the long run, are harmful to the very people that the statement seeks to benefit.

If the passing out of existence of a corporation such as The William Davies Company, or if nationalization of packing houses would materially and permanently reduce food prices, then in view of the present world tragedy it ought to be consummated without delay. The fact of the matter is, however, that with millions of people in Europe turning from producers into consumers because of war, and the tremendous destruction of food products incident to war, there is no remedy for the high prices of food while such conditions last, except the remedy of thrift and increase of production.

Long before there was talk of a Food Controller in the United States or Canada The William Davies Company urged the Government at Ottawa, in writing, to appoint a Food Controller with full power to do what he saw fit, as we realized at that time the upward tendency in the price of food commodities unless checked by official effort. At the most a great deal cannot be done in reducing food prices while currency is inflated and until the scale of prices of all kinds of commodities declines also. What can be done can only be done by a Food Controller. We wish to point out that nothing at all can be accomplished unless the data secured are accurately and clearly made and the deductions therefrom sound. Only public harm arises from dangerous incompetency in the haphazard coll lection and careless use of important figures.

As far as The William Davies Company is concerned this terminates all public statements of the Company, and it will pay no more attention to speculative and haphazard statements made either by newspapers or civil servants. The only further statement that will be made will be at an official investigation.

E. C. FOX, General Manager

THE HORSE

EDUCATING THE COLT AS FAMILY'S FUTURE DRIVER

After securing an animal with good ancestry, careful training is of primary importance in a family horse. Without this, even the most amiable beast may become a nutsance; but with it, he is of inestimable value to any household. He will not only be the idol of the most matured members of the family, but will be a reliable friend of the youngsters not yet in their teens, who are not equal to a serious contest of tugging and sawing on the bit.

In order to bring the horse to this stage of serviceableness, he must from the very beginning of his course be taught the folly of fear when under his master's hands. This requires a great deal of tact, for he must literally be taught to depend on himself, and until this is accomplished he cannot be trusted.

An undertaking of this kind is not a light one, since the trainer himself is an important factor. He must be a true friend to the young horse in order to gain his absolute confidence, which is vitally important. If in previous handling as a colt the horse has not been fooled or needlessly abused, this friendship will be readily won, at least to the extent of following his master's guidance when in the face of imaginary danger.

To say that a horse becomes like his master, may not be a very elegant statement; but it nevertheless conveys a measure of truth. If the master is rough and excitable, the horse often becomes vicious and bawky. A man with a bawky disposition should not be allowed to handle the future family horse, especially if the colt is of a sensitive disposition. In case one has a spurt of temper when around the colt, one should apologize at the earliest possible moment. Throw the arms around the neck, stroke the velvety nose; and if one feels like shedding tears, all the better—the hand will have more of the sympathetic touch so characteristic of true friendship. Five minutes of this kind of vindication will teach the colt more than several hours of whipping or driving. Anyone who is afflicted with frequent explosions of his animal nature will render a more valuable service to his country by joining the army and ventilating his passions in the war zone, than posing as an expert horseman.

A trainer's attitude toward a colt should in many respects be like that of a father to his child. The father should never punish when angry, to appease his wrath. The same rule holds true with a trainer. Remember, you are instructing, teaching, not driving. One may drive a plug, but a colt never. It is true, at times, a father or a friend must inflict pain, but he must do it tactfully and advisedly. The colt may not be as mulish as the inexperienced driver thinks. He may not know; he must be taught. There must be an understanding as to what is expected; and if true friendship exists this will be done, with gratifying results to both concerned.

In case of danger or imaginary perils it may be necessary to take a step farther than the colt. Instead of jerking or whipping, go to his head and lead him. Show him by example that there is no need of fear. Get on the side nearest to the object, and in all probability the colt will brave the danger with you. At any rate, by getting on the opposite side from which the colt is crowding, one will have control of him and there will be less likelihood of a serious accident. Most horses have sound sense and a remarkable capacity for education if subjected to a thorough course of friendly treatment.

Be patient, kind and generous. Put the colt through the grades. Give him time to become handy and useful. Too many trainers expect more rapid progress in a dumb brute than in a human being. Do not neglect his education until he has reached maturity. Handle him every day with a view of teaching him something. By all means, avoid the short course, for it is the fatal course for the family horse.

The next important factor in the education of the family horse is to teach him to drive with a slack line. By no other means will a horse gain self-confidence more rapidly than by this method. When a little frightened, he will not expect a tight rein; he has learned to keep the road without perpetual manipulation; and when he suddenly discovers an object that causes him to shy, he will take a few steps to the side and in almost the same breath be back in the road. In some instances he will stop as though for a second thought, and before the occupants will have gained a comfortable poise he will have forgotten his spurt of fright.

In training the colt this art, he must never be punished. When appearing a little frightened, introduce him to the object; let him get acquainted. Don't hurry or get excited. Pauses here are eloquent, and the colt will remember and follow his master's elementary examples by not drawing conclusions before having sufficiently investigated the fancied or possibly real danger.

HOW NAVEL ILL AFFECTS YOUNG FOALS

There is considerable mortality among foals due to navel ill or joint disease. Probably the principal reason is that cold stormy weather has been so persistent that more than the usual proportion of foals has been born in filthy box-stalls. Usually many of the late spring foals are born in grass paddocks or out in still larger and cleaner pastures. Records of navel ill cases prove conclusively that foals born in locations contaminated by manure are particulrly subject ta the disease. When foals born in pasture contract the disease it is commonly found that the spot where it was dropped was near the watering trough or feed bunk or some such location where stock was accustomed to congregate.

Several kinds of filth germs have been identified with the disease, and that is one reason for the various differences in symptoms. Another reason is that germs seem sometimes to enter the veins, sometimes the arteries, and again the bladder. Tetanus germs are present in some cases, and the foals die of lockjaw symptoms.

The best safeguard is thorough cleaning and disinfection of the box-stall in which the mare is to be put as time of foaling approaches. It should be kept clean so long as mare and foal inhabit it. Bacteriological preparations, sometimes called serums, but more properly termed bacterins, are useful, especially if administered as a preventive instead of as a cure. Some breeders and veterinarians make a practice of giving a dose of bacterin at birth and another about a week later, whether symptoms appear or not. Some begin at the mare and give 2 or 3 doses within a month preceding foaling time. Of course, the freshly severed navel cord should be disinfected, and tincture of iodine or other reasonably strong germicide is suitable for this. Such disinfection should be repeated daily until the cord dries.

If you wrap unusued silver in wax paper it will keep it from tarnishing; whiting wet with ammonia will remove tarnish.

Horses Needed for the Army

Top Prices Paid—but the Animals MUST BE SOUND

You are truly doing National Service, when you sell to the Government, horses sound in limb and body.

Every branch of the Service needs our sturdy mounts.

But inspectors are not interested in lame or blemished horses—they must be sound.

ABSORBINE

Puts your Horses in condition to command top prices

Have you a horse which might be rejected because of a Spavin, Thoroughpin, Bursal Enlargement, Shoe Boil, Capped Hock, Swollen Gland, Thickened Tissue, Enlarged Veins, Rheumatic Deposit, or any Puff or Swelling?

ABSORBINE will remove the blemish—stop the lameness—strengthen the weak part—make the horse sound.

ABSORBINE does not blister or remove the hair; absolutely safe; and the animal can be worked while being treated.

ABSORBINE is economical, because only a few drops are required for each application.

$2 a bottle—at druggists or sent post paid on receipt of price. Book "A" free.

LIVE STOCK.

THE HOGS THAT MAKE RAPID GAINS ARE THOSE THAT ARE KEPT HEALTHY

Every hog that has to feed, in addition to itself, internal and external parasites, such as worms and lice, is a source of wasted feed. Intestinal worms absorb the feed as it passes down the intestines and the common hog louse sucks blood from the hog.

Another source of loss is the direct influence these parasites have upon the vitality of the hogs. Hogs infested with parasites have their resistance to disease lowered very materially and are easy victims of disease attacks. The cases of pneumonia often occuring in bad weather, are often indirectly due to previous attacks of worms and lice. The ravages of hog cholera are increased by the lowering of vitality of the hogs.

Healthy hogs mean the maximum returns from feed given.

Worms and Their Life History

To thoroughly guard against the attacks of worms, the different worms and their life histories must be clearly understood.

At some period in the life of all worms affecting hogs, there is a time that they are out of the hog and existing in some other place.

Common Round Worms.—This is a long, yellow worm, frequently found in tangled masses in the small intestines. The eggs from the female worms pass from the hog in the faeces and are found in the soil of feed lots, stagnant pools of water, dirty drinking troughs and in the manure and bedding of the lots and quarters. Pigs feed in old feed lots, allowed to drink stagnant water from pools or dirty troughs and to root in lots that are never cleaned, pick up enormous quantities of these eggs. The eggs hatch in the stomach and intestines, begin to grow, develop into manure worms and lay more eggs. Time after time, the cycle is repeated wasting feed and debilitating the hogs in such lots and quarters.

The absolute necessity for sanitary conditions such as the thorough cleaning of feed lots at frequent intervals, the cleaning and disinfecting of quarters, the use of pure water in clean troughs of some pattern that prevents contamination by the hogs as much as possible and the use of new, clean pastures—these measures of prevention can be easily understood. There is a much greater work to be done in preventing infestation with worms than in killing them after the hogs have become unthrifty. Time spent in cleaning, disinfecting, insuring clean water and providing a rotation of clean pastures, will be time very valuably spent this summer and fall.

Thorn-headed Worm.—This is so named from the thorn-like projection on the head of the worm. The thorn is buried into the wall of the intestines, affording a safe attachment. The worm absorbs its food from the food passing down the intestines. The eggs from the females apparently pass a portion of their life in the common white grub, so common in clover sod and wood pastures. This grub is the larva of the May beetle or June bug. If a herd of hogs infested with the thorn-headed work are allowed to run in wood pastures or clover pastures, the eggs from the female worms soon infest the white grubs. Here is where trouble is stored up for future attacks upon other hogs. Non-infested pigs root up the grubs, eat them and the eggs of the worsm intestines, causing infestation.

Efforts should be made to prevent as far as possible the infestation of the white grub. If all the pigs are kept free from the thorn-headed worms, there is not so much chance of the grubs becoming loaded with the eggs. The thorn-headed worm is not as common as the common round worm, consequently is not so economically important. However, do not overlook it.

Lung Worm.—A great amount of coughing and unthriftiness in hogs is accounted for by many farmers by the supposed presence of lung worms. As a matter of fact, it is the writer's opinion that the worms are very often not present in these cases. Hogs are very subject to chronic bronchitis. due to colds and dust inhaled in dusty quarters. Draughty sleeping quarters are responsible for many cases of coughing and unthriftiness. The infestation of hogs with intestinal worms often cause general debility and the hogs may cough.

Before diagnosis of lung worms is made the presence of the worms should be demonstrated upon post mortem examination in sufficient numbers to affect the hogs. Look carefully for small, white worms in the bronchi of the lungs.

It is commonly supposed that some part of the life of these worms is spent in the soil of the feed lot. Clean lots and rotation of pastures will prevent lung worm infestation.

Kidney Worm.—This is another worm that suffers from having a very bad name. Whenever a pig or hog "goes down behind" the general diaggosis of kidney worm is commonly made. As a matter of fact, young hogs do not have kidney worms sufficiently developed to be affected. A history of a case of a hog losing control of its hind quarters other than

INTERNATIONAL STOCK FOOD COMPANY, LIMITED

TORONTO, - CANADA

THE instant lighting of any part of your home, barns, sheds is a matter only of pressing a button—if you have Delco-Light. And such a flood of clear, clean, brilliant light. Cheerful, happy light. Good for eyes. Good to keep the children at home on the farm. No matches. No smoke. No oil. No lamps or lanterns to clean.

DELCO-LIGHT

ELECTRICITY FOR EVERY FARM

Delco-Light gives pleasure and health on the farm. But it also works for its keep and pays for itself—chores are done more quickly—no lantern to hold, better light. Electric power does in half the time the milking, separating, churning, washing, and other small jobs. Saves manual labor. Saves housework. Gives running water by operating a pump. Adds all city conveniences to the farm home.

Delco-Light is efficient. It delivers all the current you need all the time, at small cost. Delco-Light is simple. There is little to get out of order. Little to do in operating. Press a lever—it starts. Stops automatically when storage batteries are full. Need be operated only two or three times a week. Full information and free literature can be obtained from your nearest distributor. Price complete, No. 208—$485 and No 216—$585.

the presence of kidney worms. An accident, feeding of unbalanced rations to sows and pigs, the suckling of a sow to a breaking point by a large litter of pigs, these are much more common as causes of trouble than the kidney worm. These causes should be promptly corrected.

The kidney worm is found in the fat and connective tissue just outside of the pelvis of the kidney. Usually the white tissues are thickened. There is very little known concerning the life history of the worm.

Treatment for Worms.

Many hog men have found that turpentine is very good for killing the worms that are found in hogs. The dosage is one teaspoonful for each seventy to one hundred pound pig. For results, the dose should be given for three mornings in succession followed by a dose of a tablespoonful of raw linseed oil. The turpentine and oil can be given in milk or slop. Don't try to drench the pigs. Get them hungry and let them drink the mixture.

A vermifuge still better than turpentine is a mixture of santonin and calomel. In the last few years, santonin has been rather difficult to obtain, but recently the supply is more abundant and more easily obtained. The most convenient method of administering is through the use of capsules or tablets. The dose is made up for each pig, and the tablet or capsule is flipped down the throat with a canine balling gun or fingers. The dose is dependent upon the size and weight of the hogs. The formula is 3 to 5 grains of santonin, and 5 to 8 grains of calomel per hundred pounds live weight. If the pigs weigh 50 pounds, the dose would be one-half the larger amounts, i.e., 2½ grains santonin, and 4 grains of calomel. If the hogs weighed one hundred pounds, the dosage would be the medium, i.e., 4 grains santonin and 6 grains calomel. When one considers there are 480 grains of santonin in an ounce of the drug and only 2½ grains is a dose for a small pig, a high price per ounce does not mean a high price per pig.

For the best results with a vermifuge, the pigs should be starved for at least twelve hours and better for twenty-four hours. This starvatiin empties the intestines so that the drugs are not diluted with a lot of feed.

Conditioners or Tonics

Unless pigs are unthrifty, the feeding of a tonic or conditioner is not advisable. Hogs if fed intelligently upon proper rations in sanitary lots, properly housed, kept free from lice and worms, and given plenty of exercise, will not need tonic. However, if a tonic is desired either of the following mixtures may be used:

1. Copperas, 3 parts; sal soda, 3 parts; Glaubers salts, 3 parts; salt, 3 parts; charcoal, 5 parts; powder and mix.

2. Three bushels charcoal; 8 lbs. salt; 2 quarts air-slaked lime; 1 bushel wood ashes; 1¼ lbs. copperas dissolved in water, and sprinkled over the mixture.

Both the adult lice and nits or eggs are killed by a thorough application of crude oil or fuel oil. Good coal tar dips kill adult lice, but they usually do not harm the eggs. In summer time, dipping tanks are the best methods of covering the hog's body with the oil or dip. In using oil, the tank is two-thirds filled with water, and from three to four inches of il is poured upon the top of the water. In winter, sprinkling or spraying with a pump or sprinkling can is advisable.

Prof. J. H. Starr.

THE VIGOROUS AND PROFITABLE SOW

There is a wide diversity of opinion among farmers and breeders of swine as to how much flesh the brood sow should carry in order that she may produce the best results as a breeder. Farmers are quite apt to neglect their brood sows and allow them to become too much run down in flesh to secure the best results, and the breeders who are anxious to obtain the best results err in the other direction and overfeed their sows until they take on too much fat to produce the most vigorous pigs.

A sow running down in flesh when bred, the same as the one too fat, is likely to disappoint her owner in the size of her litter and the quality of the pigs. The fact that a vigorous sow in comparatively low flesh will produce large litters has no doubt led to the belief that the sow should be thin when doing this important work. On the other hand the small weak pigs born to the sow in high flesh are no doubt parent to the belief that a sow should not be in high flesh while reproducing her kind.

These conclusions are correct, if appearances at farrowing time only are considered, but if the observations extend over a period of a few weeks it will be found that the fat sow and her pigs have an advantage over the thin sow and her litter. The strong pigs from the lean sow start well on account of their strength but they soon sap the stored up strength of their mother and have her exhausted before they begin to eat from the trough, with the consequent result that they come to a standstill for a time.

The smaller pigs from the fat sow grow right along from the start and by the time their dam is reduced in flesh condition they are ready to eat from the trough. The kind of flesh the sow carries has all to do with the quality of her litter. Too much fat produces fever and a lack of exercise makes her a dangerous mother. She is feverish and vicious and the pigs will suffer from this if they are fortunate enough to live. If her flesh is properly laid on by eating a variety of food, including pasture and forage crops, she will be in first class condition to give her pigs a good start in life.

It is very seldom that sows have an inclination to eat their pigs when they farrow in the pasture during the summer. A sow carrying a proper amount of flesh usually does well with her litter and she will remain quite longer after farrowing, while the lean sow will be up looking for something to eat.

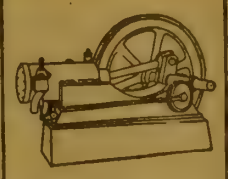
CALF REARING PRECEPTS

1. Feed regularly.
2. Feed at proper temperature, (100 degrees F.)
3. Feed individually.
4. Do not overfeed.
5. Make all changes gradually.
6. Give access to fresh water and salt.
7. Keep all utensils clean.
8. Provide clean pens with plenty of light and sunshine.
9. Provide plenty of bedding.

AN Imperial Oil tank wagon is a familiar sight in almost every city and town. Unimportant in itself, it is nevertheless an integral part of a great distributing system—a system of interest to you because it has placed within your reach the best in petroleum products at a reasonable price.

All our oils are supp ied in steel barrels and steel half-barrels — convenient, economical. No waste. You use every drop you pay for.

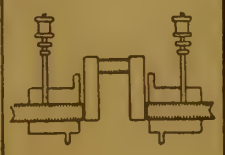
AN OIL FOR EVERY FARM MACHINE



For Gasoline Engines, Tractor, Auto or Stationary
POLARINE OIL
STANDARD GAS ENGINE OIL.
For Kerosene Engines, Tractor or Stationary
POLARINE OIL HEAVY
IMPERIAL KEROSENE TRACTOR OIL
(Recommended by International Harvester Co.)

For Open Bearings of Farm Machinery
PRAIRIE HARVESTER OIL
—very heavy body. resists cold, won't thin out with moisture
ELDORADO CASTOR OIL
—a thick oil for worn and loose bearings

For Steam Cylinder Lubrication, whether Tractor or Stationary Type
CAPITOL CYLINDER OIL
—the standard product for steam cylinder lubrication.



For Grease Cup Lubrication of Bearings
THRESHER HARD OIL
—a clean solidified oil. high melting point

AMAZON ROOFING

HERE is a ready and easy-to-lay roofing that withstands all the elements and wears indefinitely. No better "rubber roofing" could be made. It consists of a strong, fibrous, all-wool felt thoroughly saturated with non-volatile compounds. It is the high quality of this felt and the skill of saturation that make our roofings supreme. They never dry out or run. You will see this if you try Amazon Roofing.

Real Roofing Insurance

Amazon on your steep-roofed buildings means real roofing insurance. It means, first and last, the best protection against wind and weather, that you can get. Wherever you have steep roofs, use Amazon. It will pay you. Made in three different weights to meet all roofing requirements. We carry them all and can fill your orders now. Do not neglect your roofs. Fix them once for all with Amazon.

POULTRY.

PART HEN CAN PLAY IN WINNING WAR

At a public meeting held under the auspices of the Organization of Resources Committee of Ontario in Belleville recently, Col. W. N. Ponton, K.C., gave a very interesting address on poultry raising and the part the industrious hen can play in winning the war. 'Economy, always a merit, is now a virtue," said Col. Ponton, "but productiveness, of which the egg is typical, is even greater than this." In making every waste place and back yard either a vegetable garden or a chicken run, the speaker contended, there would be the pleasure and power of co-operative service; it would be educative for the boys who as poultry arisers would feel themselves factors in the community success, and even a man who cultivated the domestic virtues and domestic fowl need never fear to be hen-pecked. He would be immune. Ducks were profitable and practical scavengers and with chickens to consume the over-plus and crusts and crumbs of comfort from the kitchen, there would be no waste. With plenty of eggs and egg producers, the cold storage man and beef barons could be beaten. Col. Ponton exhibited a British Parliamentary poster showing a splendid white hen wearing a broad khaki hand emblazoned with a royal crown, and the legend "Enlisted for the duration of the war." Poultry keeping, he continued, would be an ideal occupation for maimed soldiers after the war. "Get into the winged game now," said Col. Ponton, "and help to welcome the boys home when the piping days of peace return, with 'expanding breasts and merry thoughts," and a ready prepared well basted vocation in life. Meanwhile the wishbone must be the backbone. Let there be no bone of contention. Lay a good foundation for the future; the hen will attend to the rest. This is the age not merely of public utilities, which it is our right to guard and control, but also of private utilities and opportunities which it is ours to foster and encourage—conserve and develop. Agriculture and culture can go hand in hand. There is ample room for those who have the will to work."

The industrious and productive hen, the speaker continued, could help win the war. The hen was the symbol of motherhood which the British people understood best through the mother tongue of the New Testament. "How often—as a hen gathereth her chickens under her wings," etc., were the words of the Master. Thus we could help the undoubted scarcity in the Old Motherland, which for so long sheltered us under the wings of her Fleet. "As the chain," concluded the speaker, "is no stronger than its weakest link, so the circumference can be no stronger than the centre. Britain, our centre, calls. It is our crisis. Duty, loyalty, and self interest together appeal to us all to husband and develop our living resources. Abundant food supply with universal national manhood service spell "peace with victory" for Canada and the Empire and freedom and plenty for our children's children."

POULTRY BREEDERS, ATTENTION

At the present time when growing chicks are attaining an age of from one month to ten weeks, a disease (known as Coccidiosis) affecting the liver and bowels, is causing considerable losses. This disorder, according to Dr. Wickware of the Experimental Farm, is quite prevalent throughout Canada and is probably responsible for many deaths at present attributed to White diarrhoea. The disease is caused by a small egg-shaped germ which inhabits the first portion and blind pouches of the bowels. It produces inflammation of the bowels and liver, the blind pouches showing the most marked alteration. The changes in the latter may vary from a filling up with a reddish granular looking mass of soft consistency to hard cores composed of lining cells, blood, etc. The liver may show changes varying from a fairly normal appearance to large areas of a yellow color, which when cut into show a cheese-like centre.

Symptoms:—The chicks appear dull and isolate themselves from the remainder usually remaining in the hover or under the hen. The feathers become ruffled; wings droop; appetite is lost and occasionally the chicks will give utterance to a shrill cry, particularly when trying to pass material from the bowels. A white discharge is usually present, although it may be rather reddish in colour and the vent may become pasted with the material discharged. These are the prominent symptoms in typical cases, but chicks may also be badly affected and exhibit no outward appearance of disease until death suddenly takes place.

Treatment:—Treatment consists in dissolving fifteen grains of powdered Catechu in a gallon of drinking water. This should be kept constantly in front of the chicks and should be changed every two days.

Prevention:—Prevention consists in the isolation of all ailing chicks from the remainder of the flock and the thorough disinfection of all the quarters and funs, which may be accomplished by the application of a lime-wash solution made by adding two and one-half pounds of stone lime to a pail of water, to which is also added one-half a teacupful of a good commercial disinfectant. This should be applied full strength with a spray pump, brush or old broom, to all parts of the quarters, brooder houses, etc. The feeding troughs should be cleansed daily by scalding with boiling water and special care taken to prevent the chicks from getting their feet either in the feeding utensils or drinking fountains as the disease is transmitted from bird to bird in this way. The floor of the brooder houses should be covered with a coating composed of nine parts of sand and one part of air-slaked lime, and if the droppings are not removed daily, they should at least be mixed with a fair amount of air-slaked lime to insure proper disinfection. If the runs are not large, it is also advisable to cover them with a thin coating of the above mentioned lime and either spade or plough them up. The chicks should be kept away from all adult fowls and carcasses of dead birds immediately burned, as burying only serves to keep the infection going from year to year.

PEDLAR'S "GEORGE" SHINGLES
Everywhere facts
prove the menace of lightning.
Once you realize that the danger of lightning lies in its concentrated action on a single spot in your roof, you will appreciate the safety and protection of a Pedlarized roof. Pedlar's "George" Shingles lock together on all four sides, forming a single sheet of metal from eave to ridge. Lightning cannot concentrate on any single spot, for Pedlar Shingles spread it over the whole surface of your roof. When properly grounded, a Pedlarized roof is practically indestructible. This summer know the saving and peace of mind of a safe, steel roof by Pedlarizing now with "George" Shingles. Write for the "Right Roof" Booklet M F

The Lock that Holds

WEED OUT OLD HENS AND MARKET THEM

Just after the broiler season is over, when spring chickens are scarce and the fall run of poultry has not get begun, is a good time to weed out all the hens you will not want to breed from another season and put them on the market. They will bring very fair prices at this time, if marketed in first-class condition.

They should be penned in a comparatively small enclosure and fed all they will eat for about two weeks. This fattens them rapidly unless they are over large to start with, and makes feeding profitable even at present high prices of grains.

The pen should be so arranged that the hens will have shelter from the sun during the hot hours of the day, and their sleeping quarters should provide plenty of fresh air at night.

Heavily fed hens will drink freely and they should be encouraged in this. They also need lots of grit to assimilate heavy feeding.

Feed all the hens will eat three times a day, but do not leave any soft food in the troughs between meals. Some scattered grain may be left in the pen, but not enough to prevent them from eating quantities of the soft feed which is more readily assimilated.

In the morning feed a mixture of two parts wheat middlings or "red dog" flour and one part cornmeal. Add a little salt, dissolving it in the water used in the mixture to insure even distribution. If skim-milk is available, use this instead of water in mixing the mash. Mix it into a stiff dough—the stiffer the better. At noon give a light feed of oats, and later in the day give the fowls all the corn they will eat, along with a good feed of beef scraps or cut bone.

Hens so fattened on pure, sweet products come to the table with fat globules deposited among the meat fibers, which simply melt throughout the flesh in cooking. Thus the carcass is tender and sweet, and without the stringiness commonly found in old hens. Good marketing methods often result in a gain in the price hens bring per pound, as well as in the number of pounds.

I KNOW A WOMAN'S SUFFERINGS

I am a woman.

What I have suffered is a far better guide than any MAN'S experience gained second-hand.

I know your need for sympathy and health.

And the treatment that gave me health and strength, new interest in life, I want to pass on to you, that you, too, may enjoy the priceless boon of health.

Are you unhappy, unfit for your duties? Write and tell me how you feel and I will send you ten days' FREE trial of a home treatment to meet your individual needs, together with references to women in Canada who have passed through your troubles and regained health; or you can secure this FREE treatment for your daughter, sister or mother.

If you suffer from pain in the head, back, or bowels, feeling of weight and dragging down sensations, falling or displacement of internal organs, bladder irritation with frequent urination, obstinate constipation or piles, pain in the sides regularly or irregularly, bloating, dyspepsia, extreme nervousness, depressed spirits, melancholy, desire to cry, fear of something evil about to happen, creeping feeling up the spine, palpitation, hot flashes, weariness, sallow complexion, with dark circles under the eyes, pain in the left breast or a general feeling that life is not worth living, I invite you to send to-day for my complete ten days' treatment entirely free and postpaid, to prove to yourself that these ailments can be easily and surely overcome at your own home, without the expense of hospital treatment, or the dangers of an operation. Women everywhere are escaping the surgeon's knife by knowing of my simple method of home treatment, and when you have been benefited, my sister, I shall only ask you to pass the good word along to some other sufferer. My home treatment is for all,—young or old.

Read My FREE Offer:

To Mothers of Daughters. I will explain a simple home treatment which speedily and effectually dispels green-sickness (chlorosis), irregularities, headaches and lassitude in young women, and restores them to plumpness and health. Tell me if you are worried about your daughter. Remember it costs you nothing to give my method of home treatment a complete ten days trial, and if you wish to continue, it costs only a few cents a week to do so, and it does not interfere with one's daily work. Is health worth asking for? Write for the free treatment suited to your needs, and I will send it in plain wrapper by return mail. Cut out this offer, mark the places that tell your feelings, and return to me. Write and ask for the free treatment to-day, as you may not see this offer again. Address:

MRS. M. SUMMERS, Box 309 Windsor, Ontario

FOR HOME AND COUNTRY

This Department will be utilized to the best interests of the homes in the Maritime Provinces. Subjects relating to household science and all that stands for better homes and communities will be published on this page. The editors, Misses Saunders and Winter, of Fredericton, N. B., solicite your assistance in making this page a success and will be glad to publish tested recipes, household discoveries and other articles useful to the homemaker and women's organizations.

LIFE'S WEAVER

(Wm. J. Robinson in Boston News Bureau.)

I sit today at the loom of life and
weave and weave and weave:
The warp is laid by hands divine; but
the wept is where I grieve.
For every moment in everyday the
shuttle flies through and through!
And the patterns I scheme
With the dreams I dream
Are made up of the things I do.

I have naught to do with the warp I
tread,
The threads are already set,
But my duty lies, as the shuttle flies,
In the fabric I'm weaving yet.
Smiles and tears,
Kind words and fears,
Are wound on the bobbins I wind.

And every thoughtless word is there
And every word unkind,
And every act I would fain forget,
And the thoughts that were dark
and vain,
I view in the fabric of life I weave,
And see them and see them again.
But I sit and weave with an aching
heart, and a
world of intense regret,
And tears fall fast
As I view the past,
And I pray that I may forget.

But out of repining and soul recoil
I look in the future and see,
My life stretch out in its future plan,
And a new hope comes to me.
I know not the length of the warp I
view,
I know not my given span,
But into the fabric I yet may weave,
I'll put all the best I can.
Smiles and kindness and patient care,
Unselfishness, service and love,
Harmony, sunshine, faith and hope,
And thus my contrition prove.
When the "Throw" shall fall from my
nerveless hand,
And the shuttle lies at rest,
May I hear the voice of the Master
say,
**"You've done what you thought
was best!"**

SAVING MOTHERS

The United States Department of Labor, Children's Bureau, Washington, have issued some excellent leaflets on the care of MOTHERS and BABIES, from which the following facts have been gleaned:

More women 15 to 45 years of age die from conditions connected with childbirth than from any disease except tuberculosis. About 15,000 deaths from maternal causes occur annually in the United States, and the available figures for this country show no decrease in the maternal death rrte since 1900. Maternal deaths are largely preventable by proper care and skilled attendance.

These 15,000 deaths do not measure the full extent of the waste. They are merely a rough index of unmeasured preventable illness and suffering among mothers. Furthermore, certain diseases of early infancy are closely connected with the health of the baby's mother and the maternity care she has received, and these diseases cause about one-third of all the deaths occuring among babies under one year of age. More than 75,000 babies die each year from this group of diseases because they do not have a fair start in life.

The life and health of the mother are in every way important to the well-being of her children. Breast feeding through the greater part of the baby's first year is his chief protection from all diseases, and mothers are much more likely to be able to nurse their babies successfully if they receive proper care before, at, and after childbirth.

The expectant mother should at once consult a physician. She should remain under supervision so that any dangerous symptom may be discovered as soon as it appears. She should learn how to take care of herself, and she should have proper food and rest and freedom from anxiety. When the baby is born the mother needs trained attention. A difficult maternity case is one of the gravest surgical emergencies. Many people do not seem to understand that in any case complications may arise which can be met safely by prompt and skillful scientific care but which at the hands of an unskilled attendant may cost the life of mother and child or both. Even after confinement the mother needs continued supervision and rest until her strength has returned.

Thousands of mothers, born in city and country, do not have the essentials of safety, partly, perhaps chiefly, because they do not realize the dangers involved in lack of care or else accept the dangers as unavoidable. Many women are at present unable to obtain proper care, but when all women and their husbands understand its importance and demand it for every mother, physicians will furnish it, medical colleges will provide better obstetrical training for physicians, and communities will see to it that mothers are properly protected.

Little has been done as yet to show women that much of the waste of mothers' lives and healthy is unnecessary. Even less has been undertaken by communities to provide protection for them. Many communities which have studied their typhoid and tuberculosis death rates and have undertaken costly measures to reduce them have been heedless of the death rates among mothers. It is not strange therefore that since 1900 the typhoid rate for the country as whole has been cut i nhalf, and the rate from tuberculosis has been markedly reduced, while the death rate from maternal causes has shown no demonstrable decrease.

Just how the importance of adequate maternity care is to be made plain to a community and just how skilled care and instruction are to be made available for all mothers, are of course local questions to be considered by each community. The prenatal clinics and prenatal nursing which are being developed in many cities suggest a method of supervision and instruction which might well be extended. Even in cities where such work is carried on and where good hospitals are numerous, the number of mothers reached it small in comparison with the number who bear their children without adequate means.

Difficulties are perhaps greatest in rural districts where the sheer inaccessibility of a physician is often added to the other elements of the problem. Here a public nursing service with headquarters at the county seat, or other accessible town, would probably be the first step, placing at the service of every expectant mother a visiting nurse who is especially equipped to give her information about personal care and to watch for symptoms of trouble demanding medical advice. As such a nursing service develops, its headquarters might become, with the cooperation of physicians, a sort of maternal and child-welfare center to which not only expectant mothers, but also mothers with babies could come for instruction, examination, and advice. If no general hospital were conveniently near, a cottage hospital for mothers and babies might ultimately form a part of such a center.

A more general use of existing provisions for scientific maternity care and the extension of provisions for such care in all types of communities should serve to reduce the number of deaths among mothers and babies and to improve the health and general condition of children throughout the country. A full discussion of the causes and prevention of maternal deaths and an analysis of available statistics are contained in a report on Maternity Mortality, published by the Children's Bureau.

The Children's Bureau has several publications which are of interest in connection with work for the welfare of mothers and babies. Write for this literature, which is distributed free. Be sure to ask for the bulletin on "Baby-Week Campaigns."

PATRIOTISM AND BABIES

How the strength of the nation is being impaired by the conditions which make babies sicken and die, and what some two thousand communities have done to awaken interest in the conservation of the youngest citizens, are briefly review in a new bulletin an Baby-Week Campaigns which has just been issued by the Children's Bureau of the U. S. Department of Labor.

Approximately one in ten of all the babies born in the United States dies before completing twelve months of life, and the Children's Bureau says:

"It was once thought that a high infant death rate indicated a greater degree of vigor in the survivors. Now it is agreed that the conditions which destroy so many of the youngest lives of the community must also result in crippling and maiming many others and must react unfavorably upon the health of the entire community."

Two thousand one hundred communities have reported to the Children's Bureau the details of a Baby Day or a Baby Week by which they called attention to the need of protecting their babies. Ingenious devices for exhibits, new methods of distributing pamphlets on baby care, ways in which information on local conditions are secured and published, and other interesting features from these local reports are descibed in the bulletin as suggestive for those who are planning a similar campaign.

These campaigns could easily be carried out in New Brunswick and if all societies would write for the free literature in connection with them, they would have a basis upon which to work.

SOME TYPICAL COMBINATION DISHES

Spaghetti or maraconi or rice cooked with tomato, onion, or green pepper, and cheese, or cheese sauce, served with White, graham, or wholewheat bread, and butter, and stewed or sliced fruit and simple cookies.

Boiled rice baked (scalloped), with minced left-over meat, chipped beef, or fresh or canned fish, served with beet, dandelion, or other greens, dressed with peanut, olive, cottonseed, or other table oil, with vinegar or lemon juice enough to flavor the dressing, and wheat, corn, or rye bread and honey.

Boiled rice scrambled with eggs, served with a succulent vegetable such as stewed tomatoes, canned corn, green peas or beans, and bread and butter, and nuts and raisins or other dried fruits.

Green peas and canned salmon with white (i.e., thickened milk) sauce, served with corn bread and sirup.

Meat pie (meat from inexpensive cuts) or fish pie with flour or potato crust, served with turnips, carrots, onions, or parsnips, and biscuts with butter, with jam or jelly or hot chocolate.

Mashed potato with creamed codfish, (i.e., cream sauce containing a little salt codfish), served with lettuce with oil and vinegar or lemon-juice dressing, and crackers and cheese or peanut butter sandwiches.

Meat stew (inexpensive cuts or left overs), with turnips or other vegetables, including left overs, and with rice in the stew or uour or cornmeal dumplings; or fish chowder made from fresh, canned, or dried fish, crackers, skim milk, and onion, served with bread and butter, and fresh or stewed fruit.

Boiled dinner .corned beef or corned mutton cooked with fresh vegetables, as potatoes, turnips, carrots, etc.), served with bread and butter, and apple or other fruit and breadcrumb pudding.

Cowpeas boiled with pork and combined with boiled rice, served with a green vegetable or vegetable salad, and honey, brown sugar, maple sugar, or date sandwiches.

Beans baked with pork or bacon, served with Boston brown bread and butter, and tart apple sauce and cookies.

Beans and cheese roast (a mixture of cooked beans and cheese prepared

and seasoned like a meal loaf- with tomato sauce or brown gravy, served with sweet peas and bread and butter, and sliced orange and banana or other fruit.

TO CAN FRUIT WITHOUT SUGAR

Canning Specialists Say Boiling Water May Be Used Instead of Sirup

Fruit for use in pies or salads or as stewed fruit can be canned without the use of sugar, according to the canning specaillists of the day. Any fruit, they say, may be successfully sterilized and retained in the pack by simply adding boiling water instead of the hot sirup.

Canning Fruits Without Sirup

Can the product the same day it is picked. Cull, stem, or seed, and clean the fruit by placing it in a strainer and pouring water over it until it is clean. Pack the product thoroughly in glass jars or tin cans until they are full; use the handle of a tablespoon, wooden ladle, or table knife for packing purposes. Pour over the fruit boiling water from a kettle, place rubbers and caps in position, partially seal if using glass jars, seal completely if using tin cans. Place the containers in a sterilizing vat, such as a wash boiler with false bottom, or other receptacle improvised for the purpose. If using a hot-water bath outfit, process for 30 minutes; count time after the water has reached the boiling point; the water must cover the highest jar in container. After sterilizing, remove packs, seal glass jars, wrap in paper to prevent bleaching, and store in a dry, cool place.

If you are canning in tin cans it will improve the product to plunge the cans quickly into cold wator immediately after sterilization. When using a steam pressure canner instead of the hot-water bath, sterilize for 10 minutes with 5 pounds of steam pressure. Never allow the pressure to go over 10 pounds.

STALE-BREAD RECIPES

Vegetable Soup Thickened with Bread Crumbs

1 quart skim milk, 1 cup bread crumbs, or 2 large slices stale bread, salt, small amount spinach or outer leaves lettuce (not more than 4 ounces). 1 small slice onion.

Cut the vegetables into small pieces and cook with the bread crumbs in the milk in a double boiler. If a large quantity is being prepared, as in a school lunch room, for example, put the vegetables through a meat chopper. In this case slices of bread may be ground with the vegetables in order to absorb the juice.

Pancakes

1 cup crumbs, 2¼ cups skim milk, ½ cup flour, 3 teaspoonfuls baking powder, 1 teaspoonful salt, 1 teaspoonful sugar, 1 teaspoonful melted butter, 1 egg.

Soak crumbs in milk for three-fourths of an hour. Then add other ingredients and cook on a hot griddle, like ordinary pancakes. If sour milk is used, substitute one-half teaspoon baking soda for the 4 teaspoons baking powder.

Gingerbread

1 cup molasses, ½ cup boiling water, 1 1-3 cup fine bread crumbs, 2-3 cup flour, 1½ teaspoon ginger, ½ teaspoon salt, 4 teaspoons melted lard or other fat, 1 teaspoon baking powder.

Add water to molasses and combine with the dry ingredients mixed together, then add fat, and beat. Bake for about 25 minutes in a hot oven.

Indian Pudding Made With Crumbs

1 cup fine crumbs, 1 quart skim milk, 1-3 cup sugar, ¼ cup molasses, 2 tablespoons melted butter or other fat, ¼ teaspoon ginger, ¼ teaspoon cloves, ¼ teaspoon cinnamon.

Scald the crumbs in milk; add the other ingredients; and bake 1½ hours in a slow oven. This pudding may be made with any kind of bread crumbs, but it furnishes an especially good means of using up stale corn bread.

Egg Toast.

6 slices bread, 1 egg, 1 cup milk, skim milk, or water, ¼ teaspoon salt.

Beat the egg, and add the liquid and salt. Let the bread soak in the mixture until slightly soft. Then fry to a light brown on a hot, well-greased pan or griddle. More eggs may be used if available.

THE GUARANTEE of quality that goes with every package of KING COLE TEA, is as binding to-day as it was in days before the war.

It COMPELS us to give the same exacting care in the selection and blending of teas used in each grade of KING COLE.

THE GUARANTEE is plainly printed on every KING COLE package and it is the most positive assurance of high quality that the buyer can possibly have, for it provides redress if for ANY reason there should be dissatisfaction.

The different grades of KING COLE TEA are:—

Crimson Label	-	- Today's Retail price	55c.
Green Label	- - -	" " "	60c.
Blue Label	- - -	" " "	65c.
Gold Label	- - -	" " "	75c.
King Cole Orange Pekoe		" " "	70c.

Prices may change up or down owing to market conditions but the QUALITY of each grade must be maintained at the same ORIGINAL STANDARD.

See that you get the grade you want

ST. JOHN, N. B.

HOME-MADE ICELESS REFRIGERATOR

A companion convenience to the fireless cooker for the hot, summer days is the iceless refrigerator, or milk cooler. This consists of a wooden frame, covered with canton flannel or some similar materail. It is desirable that the frame be screened, although this is not absolutely necessary. Wicks made of the same material as the covering rest in a pan of water on top of the refrigerator, allowing the water to seep down the sides. When evaporation takes place the heat is taken from the inside, with a consequent lowering of the temperature. On dry, hot days a temperature of 50 degrees can be obtained in this refrigerator. The following description will aid in the construction of this device:

How to Make Device

Make a screened case 3½ feet high with the other dimensions 12 by 15 inches. If a solid top is used, simply place the water pan on this. Otherwise fit the pan closely into the opening of the top frame and support it by 1-inch cleats fastened to the inside of the frame. Place two movable shelves in the frame, 12 to 15 inches apart. Use a biscuit pan 12 inches square on the top to hold the water, and where the refrigerator is to be used indoors have the whole thing standing in a large pan to catch any

drip. The pans and case may be painted white, allowed to dry and then enameled. A covering of white canton flannel should be made to fit the frame. Have the smooth side out and button the covering on the frame with buggy or automobile curtain hooks and eyes, arranged so that the door may be opened without unfastening these hooks. This can easily be done by putting one row of hooks on the edge of the door near the latch and the other just opposite the opening with the hem on each side extended far enough to cover the crack at the edge of the door, so as to keep out the war, outside air and retain the cooled air. This dress or covering will have to be hooked around the top edge also. Two double strips one-half the width of each side should be sewed on the top of each side and allowed to extend over about 2½ or 3 inches in the pan or water. The bottom of the covering should extend to the lower edge of the case.

Place the refrigerator in a shady place where air will circulate around it freely. If buttons and buttonholes are used on the canton flannel instead of buggy hooks, the cost should not exceed 85 cents.

FIDDLING

By George Matthew Adams in "Good Housekeeping"

FIDDLING is good for the soul—sometimes. If you fiddle away when there is important work to be done or while some one else is doing what you should do, that is not the time to fiddle. But if you have done the best you know how, and yet everybody seems to find fault with you, get your fiddle and fiddle away. It will cheer your heart, stimulate your brain, and rest your body.

But when at work, forget fiddling. Always leave the fiddle at home. In imagination, even, let not your mind go back to its fiddle.

What kind of a fiddle? There are many kinds. Not literally the one with strings. Maybe a good book, or an hour or so at a wholesome sport, or a journey among the trees and flowers and birds in the country. It's the spirit of fiddling at the right time. Old Nero fiddled away as his Rome burned. But at that, he was fairly level-headed. For could he have done anything else as effective as fiddling away at his fiddle? He wasn't the fire and hose company.

Own a fiddle of some sort, and learn to fiddle. Your nerves will thank you and your friends will thank you. But fiddle in fiddling hours.

USES OF STALE BREAD

There is nothing new in the idea of using bread crumbs in cookery, and most housekeepers are in the habit of having some on hand for use in scalloped dishes, stuffing for meat, puddings, etc. Few realize, however, how much more generally they might be utilized. Many commercial bakers use bread crumbs to some extent as a substitute for the flour in many sorts of cakes, cookies, puddings, etc. Crumbs may also be used instead of flour and starch for thickening soups and sauces.

Any bits of bread which can not be eaten at the table should be saved and crumbed for use in cooking. Some housekeepers keep two kinds on hand; one, stale crumbs made chiefly from the inside of the loaf and suitable for use in the place of flour, and dried crumbs made from any part of the bread browned a little in a very slow oven and crushed fine to be used in scalloped dishes, for the coating of croquettes or other fried foods, or wherever a crusty fine crumb is needed. To prevent their growing musty, crumbs should be kept in dry, air-tight containers. Fruit jars are often convenient for the purpose.

Toast

Toast is another form in which partly stale bread can be made attractive. In many families it is served only for breakfast, luncheon, or supper, but the custom which many high grade restaurants have adopted of serving thin, crisp, hot toast with the more substantial meals, might well be followed at home. Such dishes as chopped meat with gravy, creamed chicken or fish, poached eggs, melted cheese, cooked asparagus, Swiss chard, baked tomatoes, etc., are served very commonly on toast. Cream or milk toast (that is, toast with a rcream sauce or milk gravy, perhaps flavored with a very little chipped beef, salt fish, or other savory) may be used as the main dish at breakfast, luncheon, or supper.

As A Breakfast Food

Another good way of using stale bread or of treating bread so that it shall not become stale, is to put the pieces in the warming over or on the back of the stove and leave them until they are crisp and a delicate brown throughout. Crush with a rolling pin and use with cream as a cereal.

THINGS WORTH KNOWING

A notebook for suggestions kept in the shopping-bag will be found useful when a friend tells you of a new shop, a new recipe or a new book. Having something at hand in which to write down the suggestion will save it from being lost entirely.—Mrs. T. A.

When serving a dinner without help make a list beforehand of all the articles to be placed either on the table

GOOD MEN WANTED

in this County to retail Rawleigh products exclusively—$100.00 a month is being made by many men now selling our goods. Applicants must be live and industrious and have means for starting expenses, horse, wagon, etc., also furnish contract signed by two responsible men. Rawleigh products are household necessities—we have eight factories and branches—address, giving age, occupation and references—

Weak From Birth

Harriston (Ont.) Child Saved by Dr. Cassell's Tablets.

MR. CORBY, HARRISTON P.O., ONT., writes:—"Just a few lines in praise of Dr. Cassell's Tablets. Our little girl was weak from birth, and though we tried doctor's medicine and other things she got no better. She just lay in her cot and cried, and neighbours all said we could not save her. Then I read about Dr. Cassell's Tablets. I said to my wife, 'while there's life there's hope'; we will try these Tablets. We did, and from the first box we could see a change in the child. She seemed to rest more comfortably, and slept well at night. We kept on giving Dr. Cassell's Tablets till she was 18 months old, and now at three years I don't think there can be a healthier child in the whole Dominion.

Little Miss Corby.

The doctors said she had stomach trouble, and that her chances were small, yet Dr. Cassell's Tablets cured her. They have been worth their weight in gold to us, for we were just giving up hope of saving our little daughter. I don't think there is any other medicine for children like Dr. Cassell's Tablets. I may say my wife has taken them for nerves, and they have built her up splendidly. Publish this letter if you like; it may help others as the Tablets helped us."

Bright, healthy, happy children, full of life and activity—every mother wants her babies to be like that. Are yours? If they are not, if they are weakly or fretful we say it in all sincerity—the surest way you will ever find to build up strength and vitality in their little frames is a course of Dr. Cassell's Tablets.

Dr. Cassell's Tablets

FREE SAMPLE.
On receipt of 5 cents to cover mailing and packing, a generous free sample will be sent at once. Address: Harold F. Ritchie & Co., Ltd., 10, McCaul-street, Toronto.

Dr. Cassell's Tablets are Nutritive, Restorative, Alterative, and Anti-Spasmodic, and the recognised remedy for

Nervous Breakdown	Sleeplessness	Mal-nutrition
Nerve Paralysis	Anæmia	Wasting Diseases
Infantile Weakness	Kidney Trouble	Palpitation
Neurasthenia	Dyspepsia	Vital Exhaustion

Specially valuable for nursing mothers and during the Critical Periods of life.

Sold by Druggists and Storekeepers throughout Canada. Prices: One tube, 50 cents; six tubes for the price of five. War tax, 2 cents per tube extra.

or on the sideboard or serving-table. Prepare this list as carefully as your bill-of-fare, for by doing so you will avoid rising from the table unnecessarily, and pleasant serving is as essential to a dinner as is good cooking.—B. M. D.

Eiderdown insoles for slippers will be found nice and warm ror the mother who has to get up several times in the night to care for a baby. Slippers that can be stepped into without picking up are the easiest to wear at night, and if these extra soles are glued into them they will not feel cold to the feet when one gets out of a warm bed. —N. S. M.

Had Awful Cramps

Last Summer.

Suffered Two Days And Nights.

"Dr. Fowler's" Cured Her.

There is no other kind of disease comes on one so quickly and with so little warning as an attack of cramps, colic or bowel complaint in one form or another.

A person may retire at night in the best of health, and before morning be awakened by terrific cramps followed by diarrhoea or dysentery.

At this season of the year when bowel troubles are so prevalent, it would be wise to take the precaution of having a bottle of Dr. Fowler's Extract of Wild Strawberry in the house, ready for any emergency.

Mrs. F. Martin, Brandon, Man., writes: "Last summer, in the hot weather, I was taken very sick in the middle of the night with awful cramps. I suffered two days and nights when the doctor was called in. He prescribed pills and powders which gave little or no relief. A friend said that if she were in my place she would order a bottle of Dr. Fowler's Extract of Wild Strawberry. It came about noon, and the next afternoon I was able to sit up. I highly recommend 'Dr. Fowler's' above anything else, for I have proved it to be the best bowel complaint remedy I know of."

"Dr. Fowler's" has been on the market for 72 years. Be sure and get the genuine when you ask for it. Price 35c. Manufactured only by The T. Milburn Co., Limited, Toronto, Ont.

To keep a child in bed and prevent him from crawling up on the pillow and out of the bedclothes, as so many little children do, try the following plan: Sew two loops of tape to the middle of the nightgown hem, one in font, the other in back; then pass a long piece of tape around the foot of the crib, bringing the ends up to tie through the loops on the nightgown when the child is placed in bed. In this way the child is kept in the same place all night, though still free to turn from side to side.—Mrs. R. S. B.

To cover a comforter during the day —one which is used at night for extra warmth—take a square yard of chintz or cretonne, harmonizing with the furnishings of the room, and sew on two opposite edges a ball fringe matching the material in colors. Roll the comforter in cylindrical shape inside the cover, which should have ribbons sewed on the opposite edges to tie the quilt into the cover. This roll, placed at the foot of a bed, is easy to get at when needed and will protect a pretty new down-quilt from dust.—Mrs. R. R.

A toy watering-pot used for house plants to spray them every day will keep them in good condition all winter. Very little water will fall on the floor, and if a mop or cloth is brought in at the same time as the watering-can the water may easily be wiped up. A piece of table oil-cloth, cut carefully and lightly tacked over the wall-paper under the windows, is a good protector. It may easily be removed in the spring. Plants that barely existed through the winter in the hot, dry atmosphere of a living-room have, with the daily spraying, thrived with a greenhouse luxuriance.—A. W.

A cover for the hot-water bottle of felt or cloth, with a flap fastened by a button and loop, will be a boon to any woman who drives in the country in winter. Fill the bottle with hot water before starting out, and slip it into the case; then hold it on the knees under the rug, where the hands may be warmed alternately.—A. Z.

To be ready for next Christmas take a little notebook, attach it by a string to your desk or some other place where you will see it through the year, and in the book allow a page for each of those to whom you give Christmas presents. Try to get some gifts or to make some every month. When you have done this, cross off in the book the names of those for whom you have provided. When the holiday season comes again if you have followed this plan you will find that you have more satisfactory gifts, have felt less worry in getting them ready, and incidentally have saved some expense. —P. M.

To keep comforters clean one woman makes her sheets about eight inches longer than those generally used, having a two-inch hem on one edge; then she works three small buttonholes in the hem, one in the centre, and the other two about fourteen inches fro mthe centre, on each side. On the comforter she sews three small buttons about eight inches from the top and the same distance apart as the buttonholes in the sheets. When the bed is made up every morning the upper sheet is turned over and buttoned to the comforter, so that the sheet is always next to the face of the sleeper.—Mrs. E. P.

POISON IVY AND ITS CURE

Poison ivy is found everywhere throughout the Provinces and everyone should know how to recognize it, its effect and how to treat it. Every summer many children are poisoned with it, and many a holiday is spoiled by not recognizing the three waxy green leaves which mark this plant as different from all others. These three leaves hang down from

Eureka Potato Digger

Gets the Potatoes and separates where other diggers cannot

A strong statement, but an actual experience many times, saving growers more than the cost of the Digger. Ask us for the proof.

The Eureka elevator and duplex shaker provide more separation than other diggers. Large wheels and main gears supply ample power. Mostly malleable and steel, assuring frequent breakage and lost time. Growers report digging 80 or more acres without repairs. High clearance over shovel prevents weeds and vines bunching. Has vine-turner attachment.

6-ft. and 7-ft. sizes; several styles.

erect stems six inches to a foot high, usually three, from a woody root stock. The root is woody and tough as leather, and can be pulled out of the ground in long strings, and this is the best way to eradicate it.

The flowers form a tiny white cluster in the axils of the leaf stocks, and these turn to greenish-white berries with miridian lines. The berries stay on the plant all winter and any part of the plant is poisonous if broken. The usual poison is, no doubt, from shoe laces which have stripped off the leaves in passing through them, and the hands that lace the shoes transfer the poison to the face.

The poison is insoluble in water and so washing only spreads it. The hands should be washed in methylated spirits, strong soap or hyposulphite of soda used in photography. The druggists sell sugar of lead dissolved in alcohol, but this is a poison and should be kept from the eyes.

Almond Cake.—Beat yolks of five eggs light, add pinch of salt, juice and grated rind of one-half lemon, one cupful of granulated sugar; beat; then add one cupful of pastry flour, beat well. Fold in stiffly beaten whites of eggs. Pour into two large greased layer cake tins, and bake twenty-five minutes. For filling mix three-fourths cupful of almond paste, two yoke, two teaspoonfuls of Mocha Extract, two tablespoonfuls hot water, and one and one-fourth cupfuls powdered sugar. When cold, ice and cover with chopped walnuts.

Piles

PILES, or hemorrhoids, are the cause of keen distress to thousands who do not yet know Dr. Chase's Ointment.

There are three kinds of piles—itching, bleeding and protruding. The itching, burning sensations usually increase at night, and the misery which many people endure is beyond description. The bleeding is sometimes so profuse as to cause death. Protruding piles are most dreaded because it is commonly believed that a surgical operation is the only means of cure.

If you will read the letters quoted in the daily press there will be little chance for scepticism as to the certainty of Dr. Chase's Ointment as a cure for every form of piles. Or, better still, ask your friends about it, for Dr. Chase's Ointment is recognized among doctors and druggists as well as by the public generally as the only real cure for this wretched disease.

Dr. Chase's Ointment, 60c a box, all dealers, or Edmanson, Bates & Co., Ltd., Toronto.

machine. To get the greatest efficiency out of the machine, it must be given the best of care; and to accomplish the maximum production, the raw materials must be supplied and utilized in the most efficient way. For the farm animal, fresh air is an essential raw material, and unless it be supplied with other raw material, neither efficiency nor economy can result.

IT PAYS TO ADVERTISE IN THE MARITIME FARMER

Editor The "Maritime Farmer"

Owing to a long continued sickness, I have been unable to transact much business, and this must be my apology for delay in setting my advertising account.

In checking up my sales for the first year of advertising, I find that the cost of the latter represented less than 1½% on the total sales. Besides there is this to be taken into consideration. My stock is not a large one. Had it been so, I believe my sales would have been considerably higher and the selling cost proportionately lower, therefore. I think this is a remarkable showing and I thought you might be pleased to know of it. As an instance to demonstrate the effectiveness of advertising in the Maritime Farmer, I may inform you that the young bull which is described in my present advt. was sold within a week after it appeared. (This advt. ought to have been taken out after its first insertion, but owing to my sickness has been neglected). On another occasion where I made a quick sale, I received an enquiry and answered it, before I received the issue in which the advt. appeared! !

I am enclosing a change of copy, which please insert in next issue.

When I begin to feel a bit more fit, I propose to write you my impressions as I have received them regarding the present condition and the possible future of the pure bred live stock industry in N. B., which might be of some interest to you and to your readers.

Yours truly,
J. H. STOCKTON.

CALF NOT THRIVING

Not infrequently one of the calves in the herd may not be thriving and does not seem to chew its cud.

No animal can have a "cud" unless there is coarse food in the rumen to be re-masticated. The word "cud" is a misleading term anyway, as properly speaking there is no such a thing. The process of digestion of food in the bovine, in a word is somewhat as follows:

When coarse food is taken into the stomach it is partially chewed and then passed through the gullet into the first stomach or rumen, where the food is softened by being rolled about and mixed with the juices secreted in the paunch. The walls of the rumen then contract and force the food back again into the lower part of the gullet, which then takes on a reverse action and forces the food up into the mouth, where it is chewed over again. In swallowing the second time when fine, the end of the gullet is closed and the food forced into the second stomach. It is here again mixed with other juices and passed on to the third stomach, thence to the fourth and finally into the small bowel, where it is acted upon by the bile from the liver and pancreatic juices, where the nourishment is taken out and the refuse passed off and out of the body through the large intestine.

In order to diagnose a case, one must know more than the simple fact, that an animal is not well or that it does not chew its cud, although the latter is indicative of stomach disorder, if the calf has been feeding on coarse food, but may also be the result of other causes.

In cases of this kind it is probable that the calf's diet has not been favorable for good thrifty development and you will have to begin over again and correct this as far as possible.

The following treatment is suggested: Give two or three ounces of castor oil and after this has worked off get one-half pound each of hyposulphite of soda and gentian, mix well together and give one-half teaspoonful twice a day in two quarts of fresh, warm, sweet milk. Keep up this treatment until the calf begins to gain nicely and then increase the feed and gradually change to skim milk and give tender grass, clover or alfalfa and equal parts of oil meal, bran, corn meal and ground oats mixed and fed dry. Give only a small amount at first and increase as the calf improves in condition and growth. Give all the fresh, clean water the calf will drink and keep all pails from which it is fed scrupulously clean.

CARE OF CALF'S DIET

If we are ready to admit that a cow's milk is too good for a cow's calf and that it is economically profitable to rob the future cow for the sake of present gains, then it is quite un-

Had To Sit Up To Sleep

Her Heart Was So Bad.

Through one cause or another a large majority of people are troubled, more or less, with some sort of heart trouble, but when it starts to beat irregularly, and every once in a while pains seem to shoot through it, then it causes anxiety and alarm.

Milburn's Heart and Nerve Pills will give prompt and permanent relief to all those suffering from any weakness of the heart or nerves.

Mrs. A. Russell, Niagara Falls, Ont., writes: "At nights I could not sleep, and had to sit up in bed my heart would beat so fast.

When I went to walk very far I would get all out of breath, and would have to sit down and rest before I could go any further. I was advised to get Milburn's Heart and Nerve Pills, and before I had used two boxes I could sleep and walk as far as I liked without any trouble."

Milburn's Heart and Nerve Pills are 50c. per box, at all dealers or mailed direct on receipt of price by The T. Milburn Co., Limited, Toronto, Ont.

necessary to know how to raise calves on separator milk or other artificial and unnatural foods.

The usual practice is to pour separator milk, sometimes cold, into a large trough which is never cleaned, and allow the calves to drink until they are satisfied. This method means potbellied, runty calves that never make the growth they should, even though they fortunately escape the ravages of indigestion.

Calves should not be given quite enough milk to satisfy their appetites. Each calf should be fed separately, carefully regulating the amount of milk by the size of the calf. The fat that has been removed by the separator may in a way be supplied by adding a handful of flaxseed meal to each bucket of milk. After drinking the milk, the calf will be kept busy eating the meal instead of sucking another calf's ears. The milk should always be warm, but never given to the calf directly from the separator, when it is frothy.

The milk buckets should be taken to the milkhouse or kitchen and sterilized at least once a day. Calves will soon begin to eat a little hay, and grain, like ground oats, should thereafter constitute part of the food ration.

If it pays to raise calves at all it pays to feed and care for them from the day they are born. Farm sanitation is the all-important thing in the care of live stock on the farm.

PRACTICE ECONOMY IN USING GASOLINE

Too great care cannot be exercised in the storage of the reserve supply of gasoline. Gasoline is very volatile, that is, it evaporates rapidly at all ordinary temperatures, and the vapor will make its way through very small orifices. For this reason old and battered gasoline cans, or cans which are not fitted with screw tops, are wasteful and dangerous. With the idea of securing both economy and safety, the gas engine owner should use extraordinary care in storing his gasoline in properly constructed and vapor-tight receptacles, that si if it is impossible or impracticable to store underground, incomparably the best way to do. Putting perfectly good dollars into gasoline and then allowing it to evaporate is mighty poor economy.

As a matter of fact, gasoline is so volatile that it will evaporate to some extent even when the temperature is very low. Of course, the higher the temperature the more rapid the evaporation. Because exposed gasoline will in time disappear entirely through the process of evaporation, one might get the impression that the whole bulk of the fluid is equally volatile. This is not the case, however. Gasoline is a mixture of compounds of different specific gravity, and when it is exposed to evaporation the lighter compounds are vaporized first. Now, it is just these lighter portions of the mixture which give gasoline as a whole its life and kick, and when these are allowed to evaporate, the quality of what is left behind necessarily suffers. What remains will of course operate the engine, but it will be deficient in quality and will not permit the engine to develop its full power.—A. B.

PROTECTION OF CROPS

Crop protection means crop production. Canada loses over one hundred million dollars worth of her staple crops every year through the depredations of insect pests. A large portion of this loss could be prevented. As we cannot afford to lose the smallest portion of our grain and other food crops during the present critical period when the production of food is of supreme importance, the Dominion Department of Agriculture is making every effort to prevent, so far as possible, losses due to insect pests. Crop protection must go hand in hand with crop production.

Insect pests are not usually noticed or reported until they have caused considerable damage. Therefore it is urged that the closest watch be kept on all crops for the first appearance of any insect pests or damage. Immediately such damage is observed steps should be taken to control the outbreak in its incipient stage. If the pest or the method of control is unknown specimens of the insect and its injuries should be sent at once to the nearest of the following sources of expert assistance: The Agricultural Colleges, the Provincial Departments of Agriculture or their local District Representatives, the officer in charge of the nearest Dominion Entomological Station, or direct to the Dominion Entomologist, Department of Agriculture, Ottawa, for examination; and advice in regard to control measures will be furnished without delay. Letters and packages up to 11 ounces in weight may be mailed to the Dominion Entomologist, "Free," but postage will be required on letters or specimens sent to the other sources of advice mentioned.

Do not delay reporting insect outbreaks or sending inquiries; delay may involve serious losses that could otherwise be prevented. Write immediately, or telegraph if the outbreak is serious. Clean farming, the securing of vigorous growth in young plants and good cultivation are the best protective measures against insect attack. Keep all crops constantly under supervision for the first appearance of any damage in order that it may be checked without delay. Increased crop production involves increased protection against pests.

WHY SOILS PRODUCE POOR CROPS

Among the causes which may render land incapable of bearing satisfactory crops, the following may be mentioned:—

Want of lime may induce sourness. Its absence also affects the growth of many crops for which it is an essential plant-food particularly leguminous crops, lucerne, clovers, etc. Its presence or absence modifies the texture of the soil, clayey soils in which lime is deficient being generally much harder to work when wet and less friable on drying than those which are sufficiently supplied with it. Soils which are deficient in lime are less favourable media for the development of micro-organisms, particularly of the nitrifying orgasisms.

Deficiency in humus is a common cause of infertility. A soil deficient or wanting in humus is less able to withstand the droughty condition, lacks cohesion, and is easily blown or washed away, and is unfavourable to the growth of micro-organisms.

The remedy is to apply vegetable matter which, by its decay, will provide the necessary humus. This can be done by green manuring, by ploughing under stubble, by addition of garmyard or compost manure, etc.

Absence of bacteria, particularly of the nitrifying organisms, is prejudical to the satisfactory production of crops. The cause is generally one or other of those discussed above, either want of aeration, lack of lime or vegetable matter, sourness, badtillage or drainage, etc., and when such soils are restored to good condition the development of the nitrifying organisms will proceed normally.

Want of plant food is, of course, a common cause of infertility, especially in the case of land which has been exhausted by repeated croppings without manuring or rotation. Proper manuring, having due consideration to the requirements both of the soil and of the crop, is the remedy, provided that the land is in good condition; but the important fact must not be lost sight of that the mere addition of plant food is not sufficient unless the soil is in such mechanical condition that it can make good use of the manure applied.

Manuring alone is not likely to be of any benefit on land that is badly drained, sour, or in bad tilth.

SECOND HAND IMPLEMENTS ARE USUALLY USELESS

Habits grow. Some men seldom or never purchase any second-hand articles, while on the other hand some seldom or never buy anything new.

To condemn the practise altogether would be taking too radical a stand and yet there is no doubt but that many carry it too far. That there are frequently good second-hand articles for sale, no one will question, but when a man gets the habit so strongly fixed that his worn out stock is always made good in this way, he is no doubt carrying this practice beyond reasonable limits, and in whatever line he may be engaged his equipment is apt to be of a very poor quality.

Particularly is this true of the farmer buying agricultural implements. While it is true that at public sales there are often to be found in the offering implements and tools little the worse of wear, that have been taken care of and which are practically as good or nearly so as new, it is equally true that there are in almost every case some fit for the scrap heap or the firing line. This latter class is not only useless but in addition to the fact of their worthlessness there is usually a bill of expense connected with them from the start.

The age or state of repair is not the only feature to be noted in the purchase of second-hand goods. It often happens that perfectly sound and nearly new articles are positively useless. Nor indeed are absolutely new implements always useful; hence in the purchase of second-hand articles of this class one must be cautious lest he be deceived by fresh paint and attractive appearance.

While, as a rule the indiscriminate purchase of second-hand implements is poor business, and not to be encouraged for the foregoing reasons, it is plainly evident on the other hand that by using common sense and good judgment one may often secure a really good bargain. If a man is looking for a second-hand article for a certain purpose, he should first acquaint himself with the different types of machines on the market and their suitability for the work required of them. Having satisfied himself in this particular he is then and not until then, in a position to intelligently undertake the inspection of various makes of implements. In this respect, the first thing to note is the general appearance, which will indicate largely the kind of treatment the machine has been subjected to. If in a dilapidated condition, bolts loose and parts out of adjustment, it reveals bad treatment. If, on the other hand, it presents a tidy appearance with bolts tight and adjustments correct, it is quite evident that its care and usage has been wisely guarded by the operator.

The price justifiable for the second-hand article depends upon the condition it is in at the time of sale, and the terms upon which it can be bought as compared with a new machine. As a rule, unless the implement in question is in exceptionally good repair, not more than 50 per cent. of its original value should be paid, and yet there are cases in which a man would be justified in paying 75, 80 or even 90 per cent., having a knowledge of the implement and the kind of treatment to which it has been subjected.

In a word, whatever one's position or experience in this matter, he should avoid allowing the practice to become a habit and decide on a purchase only after careful examination and good judgment have been exercised.

GARAGE AND TOOL HOUSE

The combination of garage and tool house is one which possesses its advantages. There is always more or less tinkering to be done about an automobile and quite as often as not some tool is desired which is not a part of the regular auto repair kit. It is easily possible when building a farm garage to make it a little larger than would be necessary otherwise and in the back end of it install a work bench and plenty of racks, shelving and drawers for keeping the small tools about the place. The cost of additional material and labor will be slight. It is well to provide a second door so that one can get in and out of this part of the structure without having to squeeze past the standing automobile. The extra door will serve also to admit plenty of light and air at the work bench.—Orin Cooker.

DEATH TO THE FLIES

At the Florida Experiment Station we have found that 10 or fifteen per cent. solution of formaldehyde in fresh milk is efficient as a solution for killing flies. It is easily made and there is but little danger of poisoning. Sprinkle the floor of the barn two or three times a day with this solution. In other words, feed the flies whenever hungry. In a day or two there will be very few flies in the barn. Like every other remedy this must be used throughout the fly season.—John M. Scott.

HAVE YOU A LADDER?

Have you a good ladder on the farm or have you a cumbersome, short, heavy ladder made of 2 x 4 with pieces of boards nailed across, some of the pieces loose at one end and some gone entirely?

A good ladder is a fine investment for every farm, and extension ladders such as painters use can be purchased nowadays for about $3, depending upon the length. They are strong and well made and will reach the top of any stack a farmer can build, or the highest point of any building on his farm.

Suppose the home should catch fire on the roof? Fire inspectors say that many of the fires in the country start from sparks on the roof. How would you gain access to the roof? Have your ladder long enough and light enough to handle easily and quickly.

WIRING SCREEN DOORS

It is a very simple matter to put screen wire on that is stretched perfectly tight and smooth, instead of baggy as commonly seen. Lay the door on the floor and attach the wire to one end. Then nail or block the door to the floor half way between the ends. Then raise each end of the door about an inch and slip a board under it; this will cause the door to bend slightly.

Now stretch the wire tightly with the hands and nail it on the other end while the door is held to the floor in the middle. The wire will stand up in the middle, The wire will stand up in the middle, but the instant the blocks are removed from the ends the wire will be drawn tight and smooth.

BREEDERS' DIRECTORY

Our charge for inserting names in this Directory is $2.00 per year for each line under each heading. Money must be paid strictly in advance. Names taken out promptly when time is up Stamps taken.

PROVINCIAL EXHIBITION HALIFAX, SEPT 12th to 20th

Keep the Flags flying and your Fair gates wide open, is the advice given to the management of the Provincial Exhibition. Exalt military service and patriotism, stimulate production in all lines of effort, by emphasizing the necessity of keeping production enterprise going at top notch.

In keeping with this advice, the Commission decided early to go on with our annual fair. The prize list was increased in the Live Stock and Agricultural Classes, which are the two principal industries to be considered under present conditions.

While not putting on any special celebration this year, the recreative end will not be neglected. People need relaxation in the present tense situation.

We have increased prizes, and are making provisions for amusements.

Nothing will be cut out, except "the wail of the calamity howler."

The Industrial part of the programme is being well filled up, and it will be up to the Live Stock and Agricultural people to do "their bit" and keep the wheels moving.

BEARINGS IN MACHINERY

A very important part of any farm machine is the bearings, which are made of various metals, according to the speed of the moving parts and the weights they must sustain. Ball bearings were formerly used quite largely and are to a considerable extent yet, for certain parts of machinery, but where there is to be heavy weight, such as in wagons, binders and tractors, roller bearings are now quite generally used. They are made of steel. In shafting, where there is much friction, bearings are made of softer metal. Babbit, made of 3 parts copper, 89 parts tin and 8 parts antimony, is commonly used in such bearings. It is well for farmers to become familiar with the kind and character of the different bearings and to care for them properly.

Two Cents a Word.

This department is one of the most valuable in the MARITIME FARMER. At a cost of only 2 cents a word, you can advertise anything you wish to buy, sell or exchange. The aderess must be counted as part of the advertisement and each initial or a number counts as one word. Cash must accompany each order and advertisement must have address on, as we cannot forward replies sent to this office. Copy must be received not later than Friday before the date of issue which will always be found on the editorial page of the proceeding issle. No black faced type or display of any kind will be allowed under this head, thus making a small add as noticeable as a large one. The rate for this column is 2 cents a word, each insertion. MARITIME FARMER, Sussex, N. B.

FOR SALE—One I. H. C. Motor Hay Press, mounted, latest pattern. Only in use a short time. In A 1 working order. For further information call and see it or write HYLAND FARM, Hillsboro, N. B.

LADIES WANTED to do plain and light sewing at home, whole or spare time; good pay; work sent any distance, charges paid. Send stamp for particulars.—NATIONAL MANUFACTURING CO., Montreal.

Canada needs what You can Save !

"What we have got to do is not only to produce, but to save !"
Sir George Foster,
Minister of Trade and Commerce.

THE part which Canada is proud to play in the Empire's war is costing more than we ever dreamed we could raise. If we are to make good financially, all must help !

If every man, woman, and child in Canada would save 15c. a day, and invest it in War Savings Certificates, we could carry the cost of the War.

War Savings Certificates make it easy for everyone to become Canada's partner—bearing a share of the burden—earning, and receiving, a share of the reward.

For every $21.50 you lend the nation now, you will receive $25 at the end of three years—an interest return of over 5%. Certificates are issued in denominations of $25, $50 and $100, selling at $21.50, $43 and $86 respectively, at any Bank or Money Order Post Office. 28

THE NATIONAL SERVICE BOARD OF CANADA,
OTTAWA.

SHOW STOCK SALE!

"Minnie Vale of Victoria," another four year old daughter of "Ida Rooker 2nd Vale," has just finished a R.O.P. record of 15.784 lbs. milk and 5.61 lbs. fat, making two daughters in R.O.M. and R.O.P., all showing a much higher milk and fat record than dams. He is also a breeder of show type as proved by his continual winnings in the (get of sire class) at all Maritime Shows.

We can sell a few grand young Bulls by him, different ages, also expect to have a show lof of P. B. and grade females at Halifax, several choice ones to freshen then.

W. M. LEA,
"RIVERSIDE FARM," VICTORIA, P.E.I.

FOR SALE

A handsome, well-grown Guernsey bull. Sire purchased from the Experimental Farm, Ottawa; dam of equally good breeding, and a heavy producer. Will be sold reasonable. Full particulars on inquiry.

SARAH E. MOSES SMITH,
Woodwards Cove, - - - N. B.

Fir Shade Farm Dual-Purpose Shorthorns !

Several years ago I imported from Ontario three Dual-Purpose Shorthorn animals, and now have in my stable at Rothesay eight representatives of this breed. Two of the females are entered in the Record of Performance, and so far have done excellent work. If you feel disposed you might drop in and see these the first time you are in the vicinity. Perhaps some time when you are coming to the city you would let me know, when I could arrange to go to Rothesay with you.

The Maritime Farmer
SUSSEX, N. B.

Let the Renfrew Sta-Rite Help You to Farm Intensively

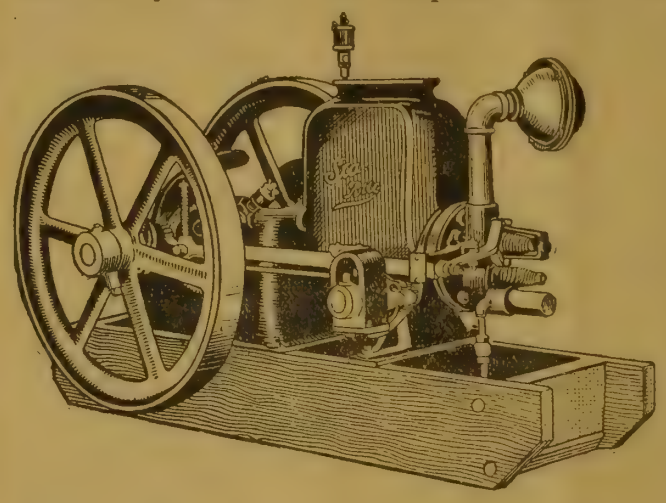
SOMEONE has calculated that it required 50,000 acres to supply the meagre necessities of each savage; while less than 25 acres are available for the exacting demands of each citizen to-day. Add to this the enormous pressure upon the farmer with the whole world pleading for more and more intensive cultivation and then you will understand why the farm gasoline engine is the farmer's "right hand man" to-day. The

Renfrew Sta-Rite

Gasoline Engine

solves the busy farmers' problem. No time has he to coax a complicated engine to do its work. This is why the extreme simplicity of the Renfrew Sta-Rite construction appeals to every farmer.

The Renfrew Standard takes in the fuel, lights the charge and evacuates the cylinders in the simplest manner with very few parts. It developes full power with less fuel.



Write for circular describing the extremely economical and simple fuel feed system the make and break igniter, the oscillating magneto and many other efficiency features that make the Sta-Rite the ideal farm engine for every kind of work.

Agencies Almost Everywhere in Canada

The Standard Cream Separator

Besides out-skimming other machines (getting all but one-tenth pound of cream per 1000 pounds of milk skimmed) the Standard is the easiest to clean. There are no milk or cream tubes to clog. The few parts coming into contact with the cream can be reached instantly. The simple bowl can be cleaned in a few minutes. Owing to the wide space between the tubular shaft and inside edges of the discs there is no choking, rending the cleaning of the discs extremely simple. The self-oiling system and oil proof housing system banish all leaks onto the frame. Write for booklet describing these and more exclusive Standard advantages.

The Renfrew Truck Scale

saves infinite bother about weighing anywhere on the farm. You can absolutely depend upon its accuracy. To every scale is attached the Government Inspector's certificate. You can weigh anything from a ponud to a ton. It wheels around like a truck. Every farmer needs one these busy days. Write for scale booklet.

Won't be at Fairs

The Standard Cream Separator will not be exhibited at the Fairs this year for two reasons:

First, because of the scarcity of machines caused by the unprecedented demand, although our output is sixty per cent. higher than any preceding year.

Second, to help reduce operating expenses during these times of war and high material costs, thus keeping the seeling price as low as possible.

TEAR OUT AND MAIL COUPON TODAY.

THE EXPERIMENTAL FARMS REPORT

The first volume of the Experimental Farms Report for the year ending March 31, 1916, contains much nformation of value to the farmers of Canada. At such a time as this when production means so much, no farmer can afford to overlook such information as this report contains, when it is understood that it is available for the asking. It represents the work accomplished on the Central Farm at Ottawa and the fifteen branch farms and stations distributed over Canada. Volume I contains the report of the Director, which is a general review of the work accomplished, also the reports of the Divisions of Chemistry, Field Husbandry, and Animal Husbandry. Volume II. not yet ready for distribution, will contain the reports of the Divisions of Horticulture, Cereals, Botany, Bees, Forage Plants, Poultry, Tobacco, Illustration Stations, and Extension and Publicity.

An interesting statement appears in the report of the Director, which deals with the cost of growing certain crops, as follows: Mangels, $1.55 a ton; ensilage corn, $1.45 a ton; oats 19.39 cents a bushel and hay $5.00 a ton. The system of farming represented in these experiments is explained in the report. It is also shown as a result of seven year's experiments that in fertilizing the soil, a distinct advantage is shown in the use of barnyard manure alone over commercial fertilizer alone. The experiments suggests the possibility of combining the two profitably when priced. Referring to new strains of priced. Referring to ne wstrains of grain being produced, it is stated that hullless and beardless barleys are receiving close attention with the promise of some exceptional results. Earlier and more productive varieties are being sought for, while new strains of oats, peas, beans, buckwheat and flax, are being tested. These are but examples of the character of the information contained in the 598 pages of this first volume that can be received, without cost, on application to the Publications Branch of the Department of Agriculture at Ottawa.

POULTRY FEED SITUATION

During the past few weeks, inquiry has been made into the poultry feed situation in the Maritime Provinces. Conditions are found to be somewhat improved over those reported a month or six weeks ago. Earlier the freight embargo and general feed shortage has almost entirely cut off the supply for many Eastern points. Latterly however, with the opening of navigation in the St. Lawrence the freight situation has improved and the principal poultry feeds are now available at larger points, although at prices considerably in excess of those prevailing in Ontario. The reports from smaller points where the demand is not sufficient to warrant purchasing in car lots, are not so favourable.

The above applies more particularly to points in New Brunswick and Nova Scotia. Prince Edward Island is largely self contained, although corn used has of course to be imported. Considerable quantities of wheat are also brought in at certain seasons.

Maritime poultrymen seem rather inclined to feed corn in excess. At present prices, crushed oats could be substituted to some advantage. Where prices are prohibited, mash feeds could also be used to replace hard grains to some extent.

He that giveth his neighbor a hunch is greater than he that driveth a 1917 model.

If You Want to Buy a Farm Inspect Land Now

The "Lay of the Land," Its State of Fertility and Freedom From Weeds May be Judged From All Angles Now While Crops are Growing---A Few Suggestions of Interest to Intending Purchasers.

By T. L. Dunkin

"Back-to-the-land" is the clarion call that rings in the ears of the urban dweller, to whom the increased cost of living is beginning to assume serious aspects. Many of our urban dwellers are beginning to look to the land as the Mecca of their desire. Scores of the boys who have returned, having done their bit at the front, as well as many of those who will return when the conflict is over, will settle on farms. The demand for farms will be great. The back-to-the-land movement will set in to stay, and as now the agriculturist will be the man of the hour.

It would not be amiss for friends to glean a lot of information about available properties that may be of service to the young men who return.

Following are some suggestions that may be of value to them:—

This is probably the best time of the year to look over a farm with a view of making a purchase. Every nook and corner shows up for just what it is worth. If the land is fertile it will show it by the luxuriant green foliage to be found growing upon it. If it is poor this fact will be revealed by a meagre growth and yellowish color. If the soil is uneven in character and a part of the field is wet and cold showing the need of underdrains, the field will be spotted and unsightly. If the ground is dirty with noxious weeds they will be easily discovered at the present time, showing up conspicuously in the grain, corn or grass fields. If there are waste places, unsightly objects and undesirable water courses they will be in plain sight now while the earth is clothed in verdure. The lay of the land and the state of the fields and fences will be easily estimated as one walks carefully and systematically over the farm. The rotation of cropping, and system of management will all be understood, and its effect on the soil readily determined. On account of the ease of and comfortable weather all parts of the farm may be readily visited and the buildings inspected and estimated as regards their convenience and suitability for the purposes desired by a prospective buyer. The general appearance and the landscape view, the attractions and value of the dwelling, the lawn, the garden and other features can all be more easily judged at this time of the year when all nature is at her best, than at any other period.

Of all the important features to be noted by a prospective purchaser of a farm that of "the lay of the land" and its character is of the most consequence. Land may be improved in many directions by a good system of farming; in fertility, by drainage, and in other ways, but the physical features and general characteristics abide always as an unchanging proposition.

Next to this comes the matter of fertility. Building up a worn out farm is a slow proposition, unless one has a large capital behind him, and his system of management includes large purchases of concentrated feeding material. Large crops right from the first are most important. Only in these lie the possibility of net profits of a farm. Poor yields usually mean no profits at all, and one's only hope of success in the farming business is by growing crops that will leave a good margin after all expenses are paid, and it must not be forgotten that it costs practically the same to grow a poor crop as a good one. In making the farm pay one must not only raise enough produce to cover the interest on investment of land, but all other expenses as well. The price of a good farm is not usually more than one-half the other expenses of the farm and frequently much less, as one will readily estimate by the use of a few figures; and since the margin of profit is usually decided by the state of fertility of a farm, being as it is the greatest factor in large production, it will, therefore, be economy on the part of a purchaser to pay a good price for fertile land rather than buy a poor quality of soil at a nominal figure.

The buildings will be the next consideration. It costs a good deal of money in these days to erect suitable buildings for carrying on a good line of mixed farming. One can afford to pay a much higher price for a farm with good buildings, adapted to the system to be followed, than for one, that has practically none suitable for the purpose for which they are intended. Inferior buildings are a big handicap to a good system of farming, and one in purchasing will be wise to allow a good figure for a farm well equipped in this respect if other things are satisfactory.

Freedom from noxious weeds is another feature of great importance to be considered. A good crop of grain or fodder of any other useful crop cannot be grown in a field badly infested with weeds and it will cost a lot of money to eradicate this nuisance from what might otherwise be a profitable farm. To eradicate some kinds of weeds from a farm means years of up hill work and one will do well to carefully consider this phase of a farm before deciding on a purchase and be willing to make a reasonable concession in price for a clean farm rather than purchase a dirty one for much less money, other things being equal A clean farm means a full crop right from the start while a weedy one means reduced or ruined crops for many years.

A poperly fenced farm also means much to a farm and due consideration should be given to the state of these farm guards. A nice crop of grain or corn growing on the farm in close proximity to a field with a poor fence where a herd of cattle are roaming over a scanty pasture in a dry time does not afford a very pleasant situation for a good restful sleep at night. Fences on a farm should be such that at all times one should have full confidence, that the live stock of a place will remain where they are put until properly removed. One who is continually living in fear of horses, cattle or other stock breaking out through a poor fence and damaging his own or his neighbors crop can have little satisfaction out of his business. Better buy a farm with good fences or have a reserve somewhere with which to build them.

Still another most important thing for observation is the water supply. Plenty of water is an absolute necessity. If it is not at hand in the form of an never-failing spring, a rock well or a running spring, one had better be sure of the practicability of securing a regular supply before deciding on any farm without it.

Again some farms have all the land under cultivation and in regular rotation, while others have a field or two in slash and which will take much labor and expense to improve and from which little revenue can be obtained for several years.

In estimating the value of a farm, reasonable allowance should be made for all the underdrains that have been properly laid. Very few farms can be at their best without a proper system of drainage, and as a rule not enough value is placed on them in estimating the worth of a farm.

In the purchase of a farm although not a part of the farm proper the market end should not be overlooked. However desirable a place may be in point of natural excellence and equipment, without a good market the enterprise must end in failure. If one is interested in the raising of heavy horses he would be foolish indeed to locate in a section of the country where dairying is the chief industry and where a carload of heavy horses could not be found suitable for the market at any price and where there is no inducement for a buyer to go. On the other hand no dairyman or breeder of pure-bred cattle should think of locating in a horse-breeding district. Invariably the best markets for any class of farm products will be found where that class is raised in sufficiently large numbers to induce buyers to visit that section for the purpose of filling their orders, for unless the farmer has the advantage of a steady and reliable market he is not in a position to make good in his calling.

More than all else the farmer should consider the family and the home in the purchase of a farm.

To raise good boys and girls is of infinitely more value than to raise good horses or cattle. To educate these and train them for useful citizenship should be the supreme consideration. Hence the conditions necessary for the attainment of this object should be studied. The moral and Christian element in the neighborhood should be unquestioned.

While the foregoing are amongst the principal items of interest to be noted in purchasing a farm, it is recognized that these are not all. As a prospective purchaser goes over any farm, if he knows farms and farming, there will usually be many things both good and bad to attract his attention and to which he will attach more or less value and which may and perhaps should have their influence on a purchase. No one farm will be found to have a monopoly of the good things and while one may excel in one direction it may be altogether inferior in another.

In this as in all other worthy lines of life's activities the motto, "First things first," should be the rule and if this is considered as a principle, the purchaser with good judgment will not likely go far astray in his choice of a farm.—O. V. J.

MEASURING UP THE FIELDS

I often wish to measure certain plots of land alone. As it is difficult to run a tape line or chain measure without help, I use the hoop method. I take a hoop from a barrel, cutting it so it will form a circular wheel 8¼ feet, or half a rod in circumference. Into this circular rim I cris-cross two light laths, making a set of spokes. In the center a hole is bored and a bolt forms a spindle upon which the wheel revolves.

A set of light handles attached to the wheel makes a light measuring barrow which is easily wheeled along and a ticker made from a corset steel tallies off the revolutions which I record as I go along. In a memorandum book I enter these figures and afterward I know to a very close fraction the number of tillable acres contained in any field on my farm.—George W. Brown.

In Marketing Poultry Distribute What You Sell Over the Twelve Months.

As a rule, the most of the market poultry sold is marketed in about one-sixth of a year, that is, in the autumn. As a result prices suddenly fall when farmers are about ready to sell. This cannot be wondered at, because when more poultry comes into the city than can be consumed as it arrives, it is necessary to put it into storage. Cold storage. unfortunately, adds to the cost which must be paid either by the producer or the cosumer, and, moreover, produce once stored is not appreciated as is the fresh quality so that poultry sold when it is not necessary to go into cold storage will bring a higher comparative price to the producer for these two reasons, writes F. E. Elford, manager Poultry Dept., Experimental Farm.

Again the remedy for this to a certain degree is in the hands of the producer. He should endeavor to distribute his produce over more of the twelve months than he does. To do this requires differest methods of handling his poultry than he has practised in the past, but such a change of methods will mean more money for the seller at a less cost of production and better satisfaction to the consumer. For instance, instead of keeping the spring chicks all summer long and marketing them in the fall, some of them at least might be marketed throughout the season as broilers. Broilers bring two or three times as much per pound in May and early June as they would bring as roasters in the fall. If, therefore, cockerels, that were large enough to be marketed at this time of the year were sold they would command, in most cases, as much per bird as they would bring if kept until fall, and the cost of production would be materially lessened. The same obtains with hens. Hens that have completed their second laying winter and have passed through the breeding season should be marketed as soon as the breeding season is over rather than be kept until the fall. Hens in June bring from '0 to 100 per cent. more than they do in October and, if marketed in June or July, do not come into competition with the cockerels which are marketed as roasters in October and November. The reason that old hens bring from 5 to 8 cents a pound in the fall is because people do not want them when they can get chickens, but, if the hens are marketed in the spring when there are no fresh roasters, the demand is good and the prices in proportion to the demand.

Broilers

Broilers are chickens weighing under 2½ pounds. Sometimes those that weigh less than 1½ pounds to the pair are called "squab broilers." The best way to feed broilers is to give a palatable mash in a clean yard, mix the msh with milk is possible, give some green food and keep everything clean and the chicks fr from lice.

When convenient, bleeding and dry plucking are advised before selling, though, if the weather is warm and local killing facilities not good, it may pay to ship alive.

Fowl

Hens that have passed their second laying season if well fleshed make excellent eating. If they have a week or ten days in the fattening crate so much the better. In selling them much depends upon the market to which you ship. In many of the larger cities the Jewish trade is considerable, they take large quantities of hens, but they want them fat and alive. For other markets it is usually the best to kill before selling. Usually any female that has laid is classed by the buyers as "fowl."

Ducks

The same may be said of other lines of poultry, especially ducks. Green ducks, that is, ducks that have just completed their first coat of feathers, should be marketed at that time rather than be kept until fall.

Large produce dealers claim that they cannot get a sufficient quantity of green ducks and are advising people to sell their ducks at 10 to 11 weeks rather than keep them until they are matured.

Geese and Turkeys

Geese and turkeys are not raised in such quantities that they glut the market materially but, in geese especially, it may not be long until they will be sold green as are ducks and will bring a larger margin to the producer. It has usually been considered that turkeys were only fit to eat when matured, but at the Central Experimental Farm this year several turkeys weighing 3 or 4 pounds each were killed and eaten and the consumers reported that the flesh was so much better than the matured bird that there is no saying what might be done with green turkeys if they could be raised in quantities.

Capons

In order to lengthen the period of marketing, the question of capons is being considered more and more every year. A caponized or de-sexed cockerel not only produces much more palatable flesh than a cockerel, but it has this advantage that it is ready to market when practically nothing else in the fresh chicken line is available; at a time when the broilers, green ducks, hens and roosters have all been marketed, and nothing but cold storage stuff is procurable. For those who can keep their birds for ten months the capons will help to lengthen the season and as consumers are willing to pay more for the superior product, caponized cockerels and probably caponized turkeys will find a place among the high-priced delicacies.

Which Hens to Market

There are some who want a limited number of eggs throughout the summer months, but do not want to keep all their hens through the warm weather. The question arises as to which hens should they kell off and which keep. To help answer this question, an eyperiment was tried to determine which hens would lay best during the summer months, also if there is any relation between winter and summer laying; that is, will a hen that lays well during the winter be more likely to lay better or worse during the summer than the hen that fails to lay during the winter months? It has been claimed time and again that it does not make any difference when a pullet starts to lay; that she will lay just as many eggs whether she starts in November or April. Our records show that the pullet that does not start to lay until near spring never catches up to her sister that begins in November or December. In this country the winters are so long that if a pullet does not lay until spring she has little more than six months to make up her number, which is a handicap she can never overtake.

To help in solving the questions referred to, we divided the pullets and hens into three groups—those that started to lay in November, those that started in January and those that started in February. Taking the three groups, we obtained the following average yield for the first two months of laying, and the four summer months, June, July, August and September. Birds starting in November laid in November and December an average of 14.8 eggs, and for the four summer months averaged per bird, 32.8 eggs. The January birds for January and February averaged 14.5, and for the four summer months an average of 30.1 was obtained. The February birds for February and March averaged 21.75 eggs, and for the four summer months averaged 27.5 eggs. So that taking the groups of birds that started to lay in the three different months—November, January, and February—their rates as summer layers were 32.8, 30.1, and 27.5 which indicates that the earlier the bird begins to lay after November 1 the more eggs will be laid, not only in the year but also in the four summer months, and therefore it is from hens that lay in the winter that we may expect eggs during the summer.

It is also generally conceded that the bird that lays late in the fall, that is, that does not moult till near winter, is the heavy layer, and when killing in the fall is practised it is not a good plan to kill those hens that are not fully feathered, as they are usually the best layers.

Distance from Market

It is a good plan to be near your market. This, however, is a relative term and does not always mean near in the sense of distance. Some people 100 miles from the market are really nearer than others within a few miles in that it does not cost as much to deliver and the produce arrives in better shape.

Distance from market should be considered not in miles, but in time, condition and expense in getting produce from the farm to the market. Two miles of rough road from the farm to the railroad station may be a greater distance than 200 miles from the railroad station to the consumer. One can be miles distant yet close enough. In the country, land is cheap, help is reasonable, feed can be bought, at first cost, and there is always the additional advantage of handling the produce of one's neighbors.

Many farmers who consider themselves out of reach of the best markets may be nearer than they think. In such cases a little co-operation may make their position ideal.

Cousnmer Pays Highest Prices

The nearer the producer can come to the consumer (that is the fewer middlemen there are) the higher will be his prices, but the greater will be the labor and expense of marketing. The best paying customers those who are williny to pay five to twenty cents per dozen above the highest retail prices—are the private families who want the best of everything and who are willing to pay for it. More attention must be given to this class, however, and all producers are not so situated that they can cater to it. Next to the family trade comes the hotel or restaurant trade, which also requires a producer close enough that produce can be shipped or delivered frequently at not too much a cost. After the hotel trade, probably the next highest prices are paid by the retail store. There are good retailers in large towns that are looking for the person who will furnish eggs regularly each week the year round at several cents per dozen above the retail store price. Some stores in cities are willing to pay considerably above the highest wholesale price for the right kind of eggs, delivered with regularity throughout the year. The only time, however, to get this or any of the other trades mentioned so far, is during the time of scarcity, not when eggs are plentiful, and it must be remembered that in these private or retail trades there will be a surplus of eggs in the spring that may have to be sold elsewhere.

The wholesale trade has received and probably always will receive the bulk of shipments. As a rule this trade will purchase any quality and quantity, though now most of them claim to be paying according to quality. It is to this market that most producers will cater, but some who are more careful in their production and who are better situated may take on the more liscriminating trade as noted above.

Protect and Advertise Yourself

Where the producer is convenient enough to a good market such as a city or a large hotel, more care should be taken in getting the eggs directly on the consumer's table, and in such cases it is generally advisable to use the dozen egg cartons. Grade the eggs according to color and size, and if they can be shipped the day they are laid so much the better. It is also a good plan for such a market to make a specialty of guaranteed strictly fresh, non-fertile eggs and to say so on the outside of the carton. In case this guarantee is printed, it is just as well to seal the carton, and as a precaution state that the eggs are guaranteed if the seal is unbroken. Should there be any likelihood of the eggs being held in the consumer's hands any length of time before being eaten, it is advisable to state that the eggs are guaranteed if eaten before a certain date, and in catering to such a class of customers the producers should candle all his eggs, for even strictly new-laid, non-fertile eggs may have a blood spot, and one such egg opened on the breakfast table will often condemn the source of supply.

For Private Delivery

Where eggs or poultry are delivered and a receipt for their delivery is necessary, the above form is convenient. The top edge is gummed and stuck to the parcel. Below the perforated line the name and amount is written and the consignee signs at the bottom. All below the perforation is retained as a voucher by the messenger.

The producer that is specializing in this new-laid egg trade and markets through the retailer should advertise himself instead of the middleman who may handle the goods., and for this purpose it is well to have the name or brand prominently but attractively placed on all the packages.

Of course, every producer is not so situated that he can cater to the highest class trade, nor is every producer qualified for taking care of such a trade. It means strict attention to detail, absolute honesty and ability to send a stated amount at stated intervals. Because of this latter fact such producers should not contract to supply every week more eggs than they have at their lowest production season, and usually during the season of high production there will be quan-

tities of eggs that will have to be disposed of in other ways. It will, therefore, be advisable, especially for producers so situated, to endeavor to have as large a proportion of their eggs produced during the slack season as possible; this will necessitate early pullets for the late fall and early winter supply of eggs.

Private Delivery Expensive

As a rule, the poultry producer cannot afford to deliver every week to private customers even though his place of business be close by. There may be an exception to this in the case of the poultry man being in the milk business where the eggs can be delivered at the same time as the milk. But to make a trip for the sole purpose of delivering a few dozen eggs is too expensive to be considered. Sending shipments by express and parcel post will be found to be less expensive, and as a rule, more satisfactory.

Extra Price all Profit

The extra price per dozen which is paid for extra quality is almost clear gain. There is a fair profit in producing eggs at the regular market prices. The largest profit must come from superior marketing and from special market advantages in selling eggs and stock. A difference of only a few cents per dozen makes a large increase in the income when several hundred fowls are kept. For example one man who has 100 laying hens from which he gets ten dozen eggs each a year, may take the wholesale price or he may send them to one of the other markets and get a premium of five cents up per dozen. Five cents on each dozen means fifty cents per hen or fifty dollars per year on the flock, which is practically clean gain, the result of good business methods, neat packages, uniformly good quality and honest dealings.

Private Trade Requires Time and Tact

Working up a first-class private trade requires time and tact. The "best advertisement is a satisfied customer." Trade grows by one satisfied customer recommending your product to another. Farmers who can reach guests at summer resorts, and those who live in communities where summer boarders are taken on the farms have a good opportunity to secure summer customers for eggs. Frequently summer hotels, restaurants, hospitals and, in some cases, large retail dealers, will pay nearly or quite as much as private families. The wholesale trade on the other hand is easier to get and easier to serve, in fact, it may be taken as a general rule that the nearer you come to the consumer, the greater tact and business knowledge are required and the greater the profit.

How to Fix the Yearly Price

In catering to a private restaurant or hotel trade, much misunderstanding may be avoided by fixing the price for the year. There are different ways of doing this. One can agree upon a stated price per dozen throughout the year and the number of eggs to be delivered each week. Sometimes the latter clause is necessary in order to insure fairness, and not to leave either party the temptation to take advantage of the other. This might be done by a dishonest producer, who could sell eggs to outside parties when he could get more for them than his contract price, or to the dishonest buyer who would purchase elsewhere when he could get eggs for less than his contract price.

Another plan is to decide upon a certain increase over the prevailing market price; for example a figure equal to 10 or 50 per cent. above the highest market quotation each week. This sliding scale proves satisfactory and there is not the incentive to either party breaking faith.

A third plan that is sometimes adopted is to fix a price per dozen for each month, varying the price a few cents, according to the demand which usually obtains at that particular season. A sample scale of prics on this basis and one which has been paid to a certain poultry man catering to Montreal private families, is: 30 cents per dozen for April, May, June, July; 40 cents per dozen for August and September; 45 cents per dozen for October and November 50 cents per dozen for December and January. 40 cents per dozen for February and March. By this system there is an incentive for the customer to eat more eggs when there are lots of them and the price low, and to find less fault if he should not get his full supply when they are scarce and the price high.

Consumer Settles Breakage Claims

In order to adjust claims for breakage with the express companies, it will be found more satisfactory to have the consumer pay the express charges. The consumer will then hold the express company responsible for rough handling. The one who is on the spot and finds the eggs broken can deal direct with the man who delivered them much more easily and satisfactorily than through a third party living at a distance. With strong, convenient, conspicuously stencilled crates, the breakage should not be serious and, if possible, avoid shipping to points where the eggs must be handled by two express companies, as each company lays the blame on the other.

Study Cow and be Able to Treat Her Diseases

Digestive disturbances among cattle are very common and are usually the result of some error in the quantity, the quality or the manner of feeding. The cow has four stomachs, or rather, four separate compartments of the stomach. The paunch, which is the largest is the receptacle that holds the food as it is first swallowed, and will hold as much as 60 gallons. This is a reservoir for the food that is eaten by the cow and is afterward remasticated. This remastification is the process that is going on while the cow is "chewing her cud", and is also known as "ruminating."

The first three compartments of the stomach are of value only in preparing the food for digestion which really takes place in the fourth part of the stomach, or the true stomach. The third part of the stomach is arranged like the leaves of a book and, after the food has been remasticated, it passes into this third compartment and is pressed and strained into the fourth stomach where the true digestive process takes place.

The feed that is given the cow should be of good quality; that of bad quality may ferment, causing indigestion and occasionally other chronic disease conditions. Feeds that contain too large a part of indigestible material to cause such a severe strain upon the digestive organs as to overwork them, thus producing diseases molds and fungi will R...
of various kinds. Feeds that are affected with the various rusts, molds and fungi will often cause severe and violent inflammation of the digestive tract, accompanied by colicky pains and diarrhoeas. They may also cause the development of dangerous and often fatal promaines.

Cows should be fed only at regular intervals and the feeding should not be done at any convenient time, as is often practised. The digestive organs accustomed to doing their work at stated intervals are not nearly so apt to become overlooked.

Feed should not be too rich in nutrients nor too concentrated, as cows are unable to subsist on feeds that do not furnish the required bulk. Cows require a certain bulk in their ration and it has been determined that a cow requires somewhere in the neighborhood of 25 pounds of roughage per day, as a necessary part of ration. If the digestive organs are not properly distended the cow will become restless and show evidence of digestive disturbance. There would be no objection, however, in feeding a concentrated feed high in nutrients and containing very little bulk by itself, if some other time in the day the required amount of roughage were fed.

Cows that have been on a fixed ration for some time should not have their ration changed suddenly. Such a change should be worked out gradually, by adding a little of the feed to which it is desired to make the change to the feed that is being used, and by decreasing the latter a little at each feeding. The digestive organs become accustomed to the work required to digest a certain feed after it has been fed for some time. The glands also become accustomed to secreting the amount of digestive secretions that are necessary to carry on digestion of the existing ration. Thus any radical and sudden change in feeds given does not allow the various organs time to regulate their function to the sudden change, and so digestive disturbances and sometimes a decided loss of weight result. Cows have been known to lose as much as 25 to 100 pounds from a sudden and radical change in the ration.

In cold weather, when it is possible, the drinking water should be heated to about 50 degrees. When given very cold it sometimes produces colic. Cows should be watered often and the water should always be pure and clean and not too cold.

Slobbering

Salivation or slobbering is a local condition and not a symptom of any such diseases as foot-and-mouth disease or rabies. Such symptoms may be caused by foreign substances, such as nails and short pieces of wire, becoming imbedded in the tongue or the cheek, or by the lodging of a foreign substance between the upper molar teeth. They may also result from eating poisonous or acrid plants or weeds, such as wild mustard. Salivation may also be caused by eating damaged or spoiled feed or sharp ensilage. If due to the feed this should be discontinued at once. As local treatment dissolve a level tablespoonful of pulverized alum in one-half pint of water and syringe out the mouth twice each day.

If it is caused by some foreign substance becoming lodged in the muscular structures of the tongue or cheek it should be removed. In examining the mouth of the cow the tongue should be firmly grasped and pulled out of the mouth and a mouth gag or a speculum should be inserted between the teeth to keep the mouth open. A mouth gag is nothing more than a small block of wood to which is attached a piece of spring metal to hold it in place and it is inserted between the molar teeth. It is safer and more practical than a mouth speculum.

The Teeth

The teeth of cows do not receive the same attention that is given the teeth of horses, yet cows have much more trouble with their teeth than the average farmer supposes. They have irregularities that may come from the unequal grinding of the teeth and from the sand that is sometimes picked up with the grass. Occasionally the teeth are broken or split by biting on some hard object that is picked up with the feed. Cavities, due to injuries to the enamel, are often found in the teeth. Ulceration of the teeth is quite common in milk cows and usually acects the upper molars. A hard swelling appears on the cow's face below the eye; it grows rapidly larger in size, is tender to the touch and the cow will often show that it is difficult for her to eat. This enlargement opens in the course of several days if it is not properly treated and then discharges a small quantity of very foul-smelling pus. Once in a while an extra tooth will be found that interferes with eating in some way; this is known as a supernumerary tooth.

To examine the cow's teeth it is necessary to use the gag or speculum previously described, and the examination should be made in a good light. If the teeth are uneven, due to grinding, they should have the sharp points removed by the same method that is used in horses. If it is necessary to extract any tooth or part of a tooth it will be necessary to cast the cow and tie her securely so that the head can be properly controlled. As soon as a swelling is noticed that would indicate there is an ulceration at the root of the tooth the swelling should be painted twice daily with tincture of iodine. If this treatment fails to bring marked improvement within a few days a veterinarian should be called to drill with a bone drill through the bone at the swelling to liberate the pus and remove the tooth, which is usually diseased, then treat as any other abscess cavity.

Inflammation of the Mouth

Occasionally, cattle are affected with sore mouth, due to eating irritant plants or spoiled feed and sometimes to sharply cut ensilage. When the mouth is examined it is found to be dry and hot; the tongue and cheeks are very red. The animal is often bothered in eating and drinking while in this condition.

If the condition is not too severe it will correct itself in a short time, otherwise the feed should be soft, and of a liquid nature, such as mashes and slops, and the mouth may be rinsed out twice each day with three or four ounces of the following solution: Pulverized alum one ounce, potassium chlorate, one ounce, and water to make one quart.

Sore Throat

This is an inflammation of the mucous membrane lining the throat and is very seldom found alone, but usually associated with some of the more severe respiratory diseases, such as pneumonia, bronchitis or pleurisy.

The muzzle is dry and the saliva dribbles from the corners of the mouth. The head is slightly extended and held rigid. The eyes are drawn so that the animal has a sleepy appearance. The animal stands quietly, scarcely changing its position, and the eyes are bloodshot. It drinks with great difficulty, and may chew some food but may drop it from the mouth rather than make an attempt to swallow it; water is taken into the mouth but instead of swallowing it the animal allows it to run out between the lips.

The water that is offered the animal should be warmed, and the feed should consist of slops and mashes and hay or linseed teas. No coarse, harsh feeds of any kind, such as hay or fodder, should be given. Take an eight-ounce bottle and in this place one ounce of tincture of iron chloride

and fill with glycerine; then place one ounce of this mixture on the tongue three times each day. Bathe well the region under the throat and between the lower jaw bones with ammonia or white liniment two or three times each day. Keep the animal in a well ventilated yet warm stall and do not allow it to be exposed to the weather or storms. Recovery should take place in from three or four days to one week.

Mumps

This is an inflammation of the parotid gland and occurs in cows of almost all ages and under almost all conditions and different kinds of care. The parotid gland lies just under the ear and extends downward to about the angle of the jaw.

This condition usually starts with a chill which is quickly followed by high fever in many cases. The head is extended as if the neck is stiff and a slight swelling is noticed in the region of the parotid gland. If only one side is affected the head will be turned to one side. This swelling is very tender to the touch and the animal will try to avoid having it manipulated. This swelling usually reaches its height in about 24 hours. The animal usually refuses all feed and may attempt to drink a little water, but may desist due to the pain it causes.

The animal should be placed in a well ventilated yet warm and comfortable box stall; water should be placed where it can be easily reached. Thin slops and mashes should be offered, but no fodders or hays. Paint the swelling three times daily for the first three or four days with tincture of iodine, and after that one each. Recovery in most times takes place in from a week to ten days, but in aggravated cases and where abscess development takes place the recovery may be delayed for three or four weeks. If abscess forms in the gland a veterinarian should be called as soon as the presence of pus can be determined by pressure of the gland with the fingers, and he should liberate the pus at once by the use of a sharp knife. The bacterin treatment as applied by veterinarians is very valuable in this condition.

Bloat

This condition is also known as hoven or tympanites. It is characterized by a filling up of the left flank and by the formation of gas. It is brought about by a wide variety of conditions, but chieby by eating spoiled feed, or feed that is wet with dew or rain, or it may result from eating too fast, which produces indigestion with a rapid fermentation asd formation of gas. It may also result from choke due to the closing of the gullet, which prevents the belching of the gas, and consequently the retention of gas causes the bloating. It may also result from the eating of frozen roots or grass, or vegetables such as turnips, cabbage and the like. It is caused most often from eating clover which is wet with dew or rain and in many cases is fatal before the animal is found. Most digestive disturbances are accompanied by bloating.

The swelling in the left flank becomes so great that it sometimes extends above the level of the back. Breathing becomes fast and difficult. The eyes have an anxious and painful expression. As bloating continues the animal shows symptoms of great pain and may reel and stagger when it walks. Death is caused from the pressing forward of the diaphragm upon the lungs, which results in asphyxiation.

If the animal is in immediate danger it should be tapped immediately. If it is not possible to procure immediately a trocar, which is made especially for tapping, use a sharp butcher or pocket knife. Do not attempt to procure antiseptics and sterilize the spot where the incision is to be made if the cow is in immediate danger. The animal should be tapped midway between the last rib and the point of the hig and about the same distance from the backbone. When the animal is not in immediate danger a rope gag is made by tying knots in a rope and placing this bunch of knots in the mouth and passing the ends of the rope up over the head, where they are tied. The animal by chewing the knots in an effort to dislodge them will cause the secretion of saliva with swallowing. The gas will then pass off by way of the gullet or oesphagus.

There are several anti-ferments that are good for treatment of bloat in preventing formation of the gas.

From 2 to 4 tablespoonfuls of spirits of turpentine given in one-half pint of linseed oil, or in milk, will sometimes be all that is required. Possibly the best treatment is one-half tablespoonful of formalin in one quart of water as a drench. This treatment has been credited to workers at the Kentucky State Agricultural College.

Urotropin is another medicine that can be used to treat bloat. It is a white granular substance with a slightly bitter taste and looks somewhat like coarse granulated sugar. It is made from ammonia and formaldehyde and should be kept in a tightly corkel bottle. Give from two to four level teaspoonfuls in a half-pint of water and repeat in an hour and a half if necessary. It is not irritating to the mucous membranes while formaldehyde is, unless it is well diluted.

Impaction of the Rumen

This condition is one of the most difficult to handle due to the fact that it is quite hard to diagnose the condition and many times the animal is overtreated. The symptoms of this condition are very irregular. It is the result of an animal eating too much food or eating feeds that were not fit for feeding.

A cow with an impaction may eat until the condition becomes very grave or she may refuse feed altogether. In all cases one can hear a grunt when the animal breathes. In some cases it can be heard all the time and at other times it may be heard only occasionally. In standing behind the cow the backbone appears to curve upward and to the left. By pressing in the region of the rumen its contents feel soft and doughy or rather firm, and the indentation made by the fist will remain for some little time after the fist is removed.

In the treatment the first and most important thing to do is to remove all feed. Water should be allowed freely. Stimulants and anti-ferments constitute the balance of the treatment. One-half teaspoonful of fluid extract of nux-vomica should be given every three or four hours and one teaspoonful of salol should be given with it to prevent fermentation. As soon as the cow begins to chew her cud and act natural she should receive a dose of castor or linseed oil. There are two operations that are necessary to cure impaction when it is determined that medicinal treatment is of no avail, but these operations can be performed only by a veterinarian.

G. H. CONN.

Where Shall the New Barn Go ?

The character of the soil upon which the dairy barn is to be situated deserves more attention than it usually receives. The location should, if possible, have sufficient slope to insure surface drainage. There is nothing much more unsanitary than to have pools of stagnant water standing around the barn. Some men realize this, and select a site that is very satisfactory from that standpoint, while from going to and fro through the country I see many barns that are not thus located. The more open and porous the soil the more preferable it is upon which to erect a building. A porous soil insures underdrainage of surplus water in the soil. This means that the lots will be drier and healthier. A dry soil exposed to sunlight is nearly the last place about the farm where bacteria will develop. One must not be misled by expecting to underdrain with tile. This method has usually resulted unsatisfactorily, for the reason that a heavy soil packs so hard from being tramped by cattle and horses that the water will pass through very slowly.

Have a southern exposure for the barn and lots. This insures more sunlight and offers protection from the cold north winds of winter. Other things being equal, it is highly advisable to locate the barn a short distance to the south of the farm grove. If there is no natural protection on the north, then a grove of quick growing trees will in a surprisingly short time make a splendid shelter belt.

Naturally the part of the barn that is to house the cows should stand north and south. Thus each side will receive the full benefit of the sunlight for part of the day. If the building stood east and west the north side would be cut off almost entirely from the sun. Getting sunlight into the dairy barn is a rather serious proposition. Not long ago I visited a dairy barn that stood east and west. There were three rows of cow stalls. The ceiling was low with a hay mow overhead.

The fact was quickly manifest that only the row of cows along the south side received a sufficient amount of sunlight. The interior gave one the impression that it never had been thoroughly ventilated. Contrasted with that, another dairy barn was visited where the large wing which held somewhere near 60 cows stood north and south. There were but two rows of stalls. The air in this barn was dry and pure, and the barn had a distinct appearance of being clean and sanitary.

Ventilation, next to and equal to sunlight, is a serious problem that confronts a man who is planning a dairy barn. The system with fresh air inlets near the ceiling and outlets for warm impure air near the bottom with an open shaft leading to the roof has been heralded as ideal. Yet in many cases, as with the barn last mentioned, it will not do the work in cold weather. The reason why it is unsatisfactory is plain. The impure air must of necessity be warmed by heat from the animals to make it lighter so that it will rise. Now cooling through the walls is done so rapidly that the impure air does not pass off or, if it does, it will be done slowly. A system of protected windows with an open air shaft from the middle of the barn that will carry off the impure air is really about as satisfactory as any that can be devised. The lower those outlets are the better it will be. Some barns equipped with them have them jointed or constructed so that they will telescope upwards to allow a wagon or the litter carrier to pass through.

Everything in the barn is, of course, to be constructed in the most sanitary manner possible. A cement floor is nearly the ideal from the standpoint of cleanliness. It is somewhat likely to be damp, perhaps. To obviate this some men are putting cement as it is being laid. About a layer of heavy tar paper in the two inches of cement is put above the paper. This seems to almost entirely do away with the dampness passing up from below. The two inches of cement are sufficient to prevent shelling off, as often happens when a thinner layer of cement is used for any purpose. Iron fixtures, stall partitions, and stanchions are quite generally used on account of their sanitary qualities.

Convenience is one of the watchwords that must be kept foremost in mind in regard to the dairy farm. A long, continuous feeding trough of cement may be used for watering the coks in their stalls. There are now in use partitions of metal for the cement mangers which can be raised mechanically. This permits the litter to be brushed out with a broom and water run in quickly and easily. There is, however, a substantial objection to watering the cows from a large open manger. That objection is that with so much water exposed in the barn the evaporation will moisten the air in the barn and make it cooler in winter time. The manger need not be deep.

To have the two rows of cows face outward is advisable for several reasons. There is more work to be done behind the cows than in front of them. There is just one alleyway to be washed each morning. The walls are never splashed up or stained, as is often the case when the cows are tied with their heads toward the inside and the litter carrier and manure wagon will pass between them.

Naturally the location of the feed room and silo may simplify or increase the amount of work required in feeding. Get the feed supply handy and make pleasure out of the work.

Ffficiency of Lightning Rods

Practically all losses from lightning are borne by farmers. In cities tall spires and stacks are occasionally struck, but ordinary buildings are practically immune. The fire marshall from Indiana in his report for 1914-15-16 shows that for these years 88 pe rcent. of the lightning losses in the state occurred in country districts. He also found that a considerable portion of the total losses, about 15 per cent., were due to lightning. Of the 5,520 buildings burned, 879 were ignited by lightning, and the loss from this cause alone totalled nearly a million dollars for the three year period. It was further shown that barns are a favorite object for lightning strokes, as high as 84 per cent. of the losses from this cause being barns.

The records of fire insurance companies show conclusively that properly installed lightning rods are efficient in preventing lightning losses. Basing his calculations on the records of eighteen fire insurance companies in Ontario, Prof. W. H. Day of the Ontario Agricultural College, states that for 1912, of 7,000 un-rodded buildings insured, 37 were struck by lightning and several were burned, while out of 7,000 rodded buildings, only two were struck and these were damaged only. This shows an efficiency of 94½ per cent. for lightning rods. A similar investigation for 1913 gave them an

efficiency of 92 per cent. Prof. Day also finds from the records of Iowa companies, that lightning rods in that state were 98.7 per cent. efficient, while in Michigan they were found to be 99.9 per cent. efficient. Prof. J. Warren Smith, of the U. S. Weather Bureau, has stated that the results of his investigations strongly substantiate those of Prof. Day.

These investigations into the efficiency of lightning rods confirm what science teaches regarding them. Lightning is an electrical discharge. Because it is electrical it must obey the laws of electricity. Men know something of the laws of electricity, and therefore they know something of the laws that govern lightning discharges. It is only reasonable to credit the men who know how to conduct mighty electrical currents into houses and buildings with perfect safety, with also being able to control conditions so that buildings may be rendered safe from lightning.

Whether the efficiency of lightning rods depends most on preventing lightning strokes, or in conducting the lightning stroke harmlessly to the ground, cannot be determined. Investigation goes to show that to a large extent their efficiency is due to prevention of the stroke. Due to condensation, immense charges of electricity are condensed on the cloud. As the positive gathers together in the cloud, the negative charge collects directly beneath in the earth. The attraction of these unlike charges causes a violent flash as soon as the electrical pressure or attraction between the cloud and earth is sufficiently high to make the electricity jump the space between them. Now, electricity it has been found will leak off sharp points. The effect of this is to reduce the potential of the charge in the earth in the immediate vicinity of the building on which these points are placed, with the result that the probability of a stroke at that point is greatly reduced. Should the stroke occur it follows the metal path provided for it to the ground and no damage is done.

In rodding a building, there are a few important considerations which must be borne in mind if the work is to be satisfactorily done, and unless it is done properly the danger from lightning is increased rather than decreased. The standard materials to use in lightning conductors are copper and galvanized iron. Iron covered with copper should not be used. To safely carry heavy lightning flashes, copper cables should weigh at least three ounces and galvanized iron five ounces per foot. All parts of the wiring should be connected up into one system with no blind ends left ungrounded. The contacts at joints should be made as perfect as possible, preferably by soldering. The cable is fastened closely to the building by means of staples, and without the use of insulators. Sharp turns must be avoided, and points or rods should be placed one within three feet from the end of each ridge. They should not be more than 20 feet apart, and one should be placed near each chimney or other high part. Those on the ridge should be three feet high and those near chimneys, etc., two feet above the highest point. On straight roofs the system should be grounded in two places, i.e. at diagonal opposite corners. If the building is over 45 feet long, a third ground should be placed near the middle of the side, the cable being joined to the main cable at the ridge. It is absolutely essential that the grounding wires reach permanent moisture, going down at least 8 or 10 feet below the surface.

TELLING AGE OF ANIMALS

The age of a horse is determined by his teeth; by the time that they appear and by the disappearance of the cups or tables.

The centre pair of the milk teeth are found in the colt's mouth at birth or a few days after. The intermediate pair appear when the colt is six to nine weeks old and the corner pair at seven to nine months. The larger permanent teeth appear at about two and a half years and re in full wear at three years. The next pair when up indicate four years and the corner ones appear at about four and a half, being in full wear at five.

At five years what are known as the tusks are full size. At six the cups have practically disappeared from the center pair of lower incisors. tA seven the "swallow-tail" or nick has appeared in the corner incisors and the cups have disappeared from the intermediate lower incisors. At eight years the cups have practically disappeared from the corner incisors. At nine, ten, and eleven the cups disappear from the centre, intermediate and corner upper incisors respectively. From eleven on the teeth become more triangular and join the jaw at a greater angle.

Cattle

Age of cattle is best determined by the teeth. The calf is usually born with two fore or cutting teeth, and in one month the entire eight are out. The age is then guessed by the wearing down of these teeth until the calf is eight months old, when they begin to grow narrower and smaller. At eight months old the two centre teeth have become smaller than the rest, and from that time until eighteen months of age the other teeth gradually diminish until they are all considerably lessened in size and stand apart from each other.

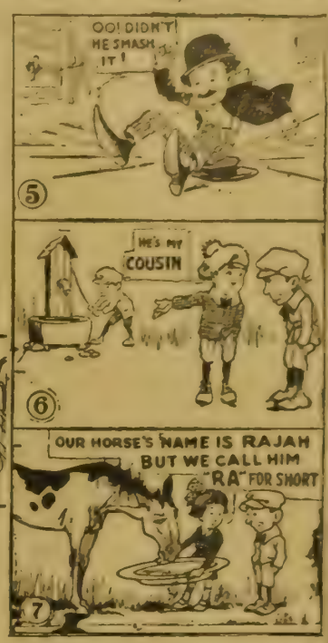
At two years old the two middle teeth are pushed out and succeeded by two permanent ones. At three years of age there are four permanent teeth, and at four years and all the rest at five years of age, when the animal is said to be full mouthed.

From six to eight years one will be guided by the wearing down of the teeth and after that by the diminution of their bulk.

At nine years of age the two middle fore teeth are smaller and narrower than the rest; at ten years of age the next two are so, and so on until the animal is twelve years of age, when the teeth again begin to stand apart from each other.

What Did We Plant in Our Vegetable Garden?

What vegetables do these pictures represent?



What vegetables do these pictures represent?

TO help win the war we must all produce, so every patriotic Canadian has a vegetable garden this year. We have a fine assortment of vegetables in our garden, and if you will study the pictures at the right you may be able to discover what we are growing. Each of the pictures represents a common vegetable that you all know. Here are two examples from the series our artist drew and we will tell you that No. 1 is Cauliflower (Call-eye-Flower) and No. 8, Beets (Bee-eats). Now see if you can solve the rest and when you have them all, write your solutions on a sheet of paper and send them to us.

This Contest is Free of Expense to All

YOU do not spend a single penny of your money, nor will you be asked to buy anything in order to enter this great Contest and win the Chevrolet Car or a fine prize. The Continental Publishing Co., Limited, one of the strongest and best known publishing firms in Canada is conducting this interesting Contest in order to quickly advertise and introduce "RURAL CANADA for Women" the wonderful new magazine for Canadian Farm Folk and landlovers everywhere.

RURAL CANADA is different entirely from any other Canadian Farm Paper, because it is edited and published mainly for the women folk in our Canadian farm homes.

AS soon as your answers are received we shall write and tell you how many of the names you have solved correctly, and send you free a copy of this month's fine issue of RURAL CANADA. Then when you know your standing for the big prizes you will be asked to help us advertise and introduce RURAL CANADA in your neighborhood by showing your copy of the new magazine to just four of your friends and neighbors who will appreciate the worth and high purpose of RURAL CANADA and want it to come to them every month. State your willingness to accord us this simple favor when you send your answers. It will only require a few minutes of your time and you are guaranteed and will be sent at once a big cash payment or valuable reward for your trouble. If you wish we will gladly send you extra sample copies to leave with your friends to read.

WHEN your answers to this interesting puzzle are received we shall gladly mail you without cost a sample copy of the latest issue in order that you and your friends may become acquainted with this great new publication and realize the place in Canadian Home Life that RURAL CANADA now occupies.

It is entertaining as well as instructive. It abounds in fine short stories, timely articles, fashions, embroideries, crochet work, recipes, a children's page, a family doctor and many other fine features. Its editorials are inspiring and uplifting. In short, to know RURAL CANADA is to love it. You and your friends will be glad to make the acquaintance of so bright, interesting and good a magazine.

Follow These Simple Rules Governing Entry to the Contest

WRITE on one side of the paper only. On one sheet of paper put your answers to the puzzle pictures, with your full name and address, (stating Mr., Mrs. or Miss) in the upper right hand corner. Anything other than this must be on a separate sheet of paper.

Boys and girls under ten years of age are not allowed to send answers to this Contest, because later on we intend to have a fine contest for our boy and girl friends. Employees of this company are absolutely debarred from competing.

To ensure absolute fairness and impartiality in awarding the prizes, the properly qualified entries will be judged by a committee of three well known gentlemen, having no connection whatever with this firm, and contestants must agree to abide by their decisions. The prizes will be awarded to the duly qualified contestants whose entries show the greatest number of correct or nearly correct names and are considered by the judges to be nearest and best written. (Prizes are paid [illegible] and every entry also has a good [illegible] A contestant may send in as many sets of answers to the puzzle [illegible] but only one will be allowed to win a prize and [illegible] Contest will close [illegible] after which the judges will award the prizes.

Send [illegible] your free sample copy of RURAL CANADA, prize list, etc.

1st PRIZE

5 Passenger Chevrolet Touring Car

And More than $1,000.00 in Handsome Prizes to be Awarded

THE BIG PRIZES [illegible] Chevrolet Touring Car, [illegible] Bicycles, [illegible] Cameras, [illegible] Mantle Lamps, [illegible] big valuable prizes too numerous to mention here.

WE WILL SEND YOU THE BIG COMPLETE ILLUSTRATED PRIZE LIST

Address your solutions to

THE CONTEST EDITOR, RURAL CANADA, 10 CONTINENTAL BLDG., TORONTO

THE MARITIME FARMER.

And Co-operative Dairyman

Registered Trade Mark

Semi-Monthly Journal devoted to the interests of the farmers of the Maritime Provinces.

Official Organ of The Farmers and Dairymen's Association of New Brunswick; The Nova Scotia Farmer's Association; The Nova Scotia and P. E. I. Fruit Growers' Associations; The New Brunswick Fruit Growers' Association; The Maritime Stock Breeders' Association; The Maritime Bee-Keepers' Association; The New Brunswick Poultry Association, and the Newfoundland Agricultural Board.

Subscription price $1.00 per year. This paper is sent to subscribers unless a definate order for discontinuance is given.

The date after your name on the little green label on front page, is in every case the time to which your subscription is paid.

OUR GUARANTEE.—With each subscriber to the MARITIME FARMER, we positively guarantee, while his subscription lasts, that no advertisement is allowed in our columns unless we believe that any subscriber can safely do business with the advertiser, and we agree to make good any loss which any such subscriber may sustain by trusting any such advertiser who may prove to be a deliberate swindler; but we do not undertake to adjust trifling differences between subscribers and responsible advertisers. To take advantage of this guarantee, written complaint must be made to the publisher within one week from the date of any unsatisfactory transaction, with proof of the swindle and loss, and within one month from the date when the advertisement appeared, and the subscriber must prove that in writing to the advertiser he said:—"I saw" your adv. in the MARITIME FARMER.

RATES FOR CASUAL ADVERTISEMENTS.

inch—First insertion 75 cents 2 inches—First insertion $1.50; inches—First insertion $2.25.

Contract rates on application.

Address letters and make all checks, money orders, postal notes, etc., payable to

British " —W. F. Watts, 145 Fleet St., London.

NOTICE TO ADVERTISERS.—Changes of ads. should reach this office one week before date of issue, in order to insure insertion.

RECEIPTS FOR FARMER SUBSCRIPTIONS

The Maritime Farmer, instead of giving you one receipt in the year for a paid subscription, sends you 24, or one every two weeks. You will find it on the GREEN COLORED LABEL on which your address appears. The date printed thereon is that on which your subscription terminates. If on payment of your subscription the date is not changed within two weeks, please notify us. No other receipt will be sent.

AUGUST 28, 1917.

DATES OF ISSUE

September 11-25
October 9-23
November 6-20
December 4-18

EXHIBITION TIME WILL SOON BE HERE

Exhibition time will soon be here. Despite the adverse seeding conditions that prevailed last May and June, the farmers of the Maritime Provinces were able to plant and sow the major portion of the areas planned for the respective crops. Growth has been rapid and present indications point to bountiful harvests. The choicest specimens of this seasons growth will be found at the fall fairs where farmers, gardeners, fruit growers and live stock breeders will exhibit and vie for supremacy.

In New Brunswick there will be only one large fair, the Charlotte County Exhibition, held in the pretty border town, St. Stephen. While this is only a county fair, the attendance usually compares favorably with that at some of the larger provincial fairs, and the exhibits in the various classes are usually of no mean order.

Of course there will be a number of small district fairs held in the province as heretofore. The St. Stephen dates are September 11th to 14th inclusive.

In Prince Edward Island the provincial fair will be held as usual in Charlottetown, from September 25th to 28th inclusive. It is always worth while visiting Charlottetown during the fair week. The admirer of good horses, cattle, sheep and swine, will find something to interest him in these lines at the Island fair.

At Halifax, the big Nova Scotia Provincial Exhibition will be held from September 12th to 19th, and farmers who wish to combine an educational trip with business and pleasure, will be well advised to visit the Garrison City while the big fair is being held.

Yarmouth and Sydney will hold their fairs later in the season. As in New Brunswick, a number of smaller fairs will also be held in Nova Scotia and Prince Edward Island.

Patronize as many as you conveniently can. You will find many exhibits that will interest you.

PULVERIZED LIME

It is a well recognized fact that a great many of our Maritime farms are composed of soils that are acid to a degree that is detrimental to the best growth of farm crops.

Next to clearing the land for cultivation purposes, the most important operation as we see it, is the proper draining off of all surplus water from the soil. The liming of the soil to sweeten it for plant growth, is the next most important factor.

Given well cleaned, well drained soil, free from excess acid, the farmer is reasonably sure of a good crop if he uses good seed and practices a good tillage system.

Many soils that have natural drainage are acid, so that the use of adequate applications of ground lime stone is indeed an important factor.

Experiments prove that it pays to use ground limestone. Several commercial plants for the manufacture of this product are in operation in the Maritime Provinces. Farmers living within a certain radius of these plants, or who have the advantage of good transportation facilities, may procure ground lime stone at fairly reasonble prices. Then there are sections remote from the lines of transportation, where there is an abundance of lime rock that the farmers may quarry and get in readiness for the government lime stone pulverizing machine, that will be sent there on application to do the work at the lowest possible cost.

It is well for farmers who reside where there is an abundance of limestone, to write their Department of Agriculture, setting forth the conditions that exist in their locality, and make application for a demonstration. We have seen this work done in several localities, and we have noted the beneficial results accruing from the use o fthe pulverized lime stone thus produced. We believe the time is not far distant when lime pulverizing machines will be available in many sections where limestone is available, and it will be over the very best and most profitable community investments.

Such an outfit is not expensive and it is easy to operate with power already at hand; it is just one more means of keeping the engine busy at a profit.

The pulverized rock is the proper means for liming the soil. Burned lime is sometimes recommended as being the best to use. But successive years of comparative trials in the fields of various experiment stations have demonstrated that pulverized limestone is likely to produce better results than burned lime. It is also safer to use; since it has no injurious effect whether applied at any time or in any quantity.

An item that will interest the prospective buyer of a lime pulverizing machine is that it is not important to have the limestone ground extremely fine. Continued experiment has demonstrated that if the stone is ground fine enough so that it will all pass a sieve with 10 meshes to the inch, and contains all the fine material produced in grinding it to this degree, it is as fine as need be for practical use. So that a portable crusher is very practicable, not only because of the opportunity it offers for profitable work for the engine, but as the indirect means of increasing the productiveness of all land in the neighborhood. As an instance we quote a New York agricultural experiment station bulletin stating that three-fourths or more of the farm lands of that state would be greatly benefited by a liberal application of lime in some form. In fact, such a treatment is fundamental to any rational method for improving these soils.

SAVING THE CALVES AND LAMBS

People who think that every piece of veal they see served means diminishing the supply of milk or of beef in the future are mistaken. Most of the calves used for veal are fit only for veal. They would make neither good milch cows nor good beef cattle. They aren't bred of the proper stock for either. They are defective in both ancestry and architecture.

Most of the veal calves butchered in this country come from the dairy farms. The average dairy farmer is inteested only in milk production. His cows are bred usually to any kind of bull and their calves taken from them as quickly as possible, so that the milk may be had for market. Were these cows bred to high grade beef bulls, their calves could either be raised by the dairy farmer and sold for beef, or sold to some other farmer who would so raise them. But as it is, the ordinary calf that is sold for veal would not be worth as beef the cost of the grain to fatten it. Therefore its only value is as veal. This does not apply to the up-to-date dairy farmer who breeds his cows to pure bred bulls of breeds known for their milk production. These calves are too valuable to be sold for veal and are raised. So too are the calves of well graded beef herds, whether on the farm or range. The delicacy known as veal comes chiefly from the dairy herds near our large cities and would be a losing proposition for any man who tried to raise him for beef.

But young ewe lambs should not be eaten. The world in general and this country particularly is short of wool and breeding sheep, so short that we ought to raise all the ewe lambs that are fit to raise for breeding. And most ewe lambs are because the sheep raiser knows that he must have good stock to get good wool, so the majority of the ewe lambs are fit to raise. The lambs, if raised, produce regular crops of wool and also when they grow up furnish a greater supply of mutton.

Meantime, while we are seeking ways and means of stopping waste and saving our meat-producing animals, if people would use the cheaper cuts of beef, and study how to prepare them in the appetizing ways that are possible, that also would help a lot to relieve the situation.

REVIVAL IN SHEEP INDUSTRY

Interest in sheep raising is rising rapidly. The prices current for wool, mutton and lamb explain this interest. Some farmers hesitate to invest on account of the ravages of dogs, but every business has its perils.

The recent changes in the Sheep and Dog Act in New Brunswick gives the sheep breeders of the province better protection than is enjoyed by their fellow breeders in the other provinces.

Save the young ewes and ewe lambs this fall and breed them to the best pure bred ram you can afford. The industry is booming and is bound to boom for many years. Be ready to share in the profits.

* * *

This is the dawn of the tractor age, and he is wise who investigates its possibilities, forecasts its future, and shares in its opportunities and benefits.

CURING CLOVER BLOAT IN CATTLE AN EASY MATTER

Tympany, or bloating, in cattle may follow the ingestion of certain foods. A sudden change from dry feed to a green, succulent feed of any kind may induce bloating. Alfalfa and clover, especially the red and white varieties of clover while in flower, are particularly dangerous in this respect. Turnips, potatoes and cabbage may induce bloating; middlings and corn meal frequently do so. Grass or clover, when wet with dew or rain or when covered with hoar frost, should be regarded as dangerous.

As a rule the onset of bloating is rather sudden. The animal is nervous, moves uneasily, and is distressed. The swelling of the left flank is characteristic and in marked cases the upper portion of the flank rises above the level of the back, and when struck with the fingers resounds like a drum. The breathing becomes more difficult, the animal reels on walking or standing, in a short time falls and, if not allowed, dies of suffocation.

During the spring of 1913 several cases of bloat occurred in the station dairy herd and our attention was called to the necessity for further study of this condition. Following the unusual production of clover in the pastures in 1913, the growth of grass in the spring of 1914 was so luxurious that little clover appeared and we did not have a single case of bloat in 1914. During the spring of 1915 the clover was again returning and five cases of bloat occurred in the dairy herd. The spring of 1916 presented the banner crop of clover in the pastures, in many cases the clover blossoms at a distance resembling snow. This spring also afforded a large number of cases of bloat, the first before the clover blossoms.

We were able to demonstrate that red and white clover blossoms alfalfa blooms and, in seasons of luxuriant growth, clover leaves contain sufficient quantities of sugar, and are contaminated with sufficient numbers of either wild yeasts or sugar-splitting microorganisms to cause an active fermentation in the rumen of cattle eating these substances heartily. This process is a true fermentation.

In clover bloat an ounce of prevention is worth a pound of cure. When, in the spring, cattle are first turned on clover or other greed feed the change should be made gradually, and this is best accomplished by having the cattle graze for 20 to 30 minutes the first day, increasing this period each day until the digestive organs become accustomed to the green, succulent feed. During the early weeks of spring, cattle should not remain in the pasture over night nor be turned on pasture while the dew or frost is on the grass. An excellent practice is to feed cattle a little hay or other dry feed just before turning them on pasture. Watchfulness during a week or two of early spring will prevent many cases of bloat.

When bloating does occur it may be promptly relieved by drenching the animal with one quart of a 1 ½ per cent. solution of formalin in water, at the same time propping the mouth open with a block of wood and, if possible, inducing gentle exercise. After the animal has recovered, a second drench, composed of 1 pound of Epsom salts and ½ ounce of ground ginger in 1 pint of tepid water, should be administered. Formalin is a trade name for a 40 per cent. solution of formaldehyde gas in water and may be obtained in any drug store. One-half ounce of formalin added to 1 quart of water makes the proper solution with which to drench the animal.

During the past 4 years we have used this formalin treatment for clover bloat with marked success. During this period we have had 18 cases of clover bloat in the experiment station dairy herd. Two of these cases died before any treatment could be used. The remaining 16 received the formalin treatment, and 14 of them promptly recovered in from 20 minutes to an hour. Two of the cases did not recover promptly and were punctured, after which they promptly recovered. Two of the cases went off feed and the milk diminished following the clover bloat with formalin treatment, but returned to normal after a few days.

In severe cases it becomes necessary to puncture the paunch. In such cases this should be promptly done. The instrument used for this operation is made in two parts, a trocar fitting within a canula, similar to a sword in its scabbard. This instrument is first sterilized by boiling for a few minutes in water containing a small quantity of washing soda, or by immersing in 50 per cent alcohol for 5 to 10 minutes. The sterilized instrument is then boldly plunged through the skin of the animal's left side, midway between the last rib and the hip bone, into the paunch. Then the trocar is withdrawn from the canula, which remains in position and allows the gas to escape from the pounch. This operation will be less dangerous if the animal has been first drenched with the formalin solution. When the animal is relieved the Epsom salts and ginger drench should be administered.

SAFETY MEASURES TO ADOPT IN A LIGHTNING STORM

It may comfort those who dread the approach of a thunderstorm to know that here in Canada the average person is ten times more likely to be drowned or fatally shot than to be killed by lightning. Moreover, of every three persons actually struck by lightning, two probably will survive the shock.

Thunderstorm frequently seems to depend upon the moon's phases, according to statistics gathered by Professor W. H. Pickering, the astronomer of Harvard University. According to his tables we may look for such outbursts particularly between new moon and first quarter, while they are fewest between full moon and last quarter. If this rule may really be depended upon, it is safer to go camping when the moon is shrinking than when it is swelling.

The oak is the most dangerous and the beech the safest tree to stand under during a thunderstorm.

The oak is struck fifty-seven, the fir thirty-nine and the pine five times as often as the beech. Statistics for other trees are too scattering for comparison Many people have believed that the beech, birch and maple are never struck, but this is untrue, although these trees are seldom struck. The oak suffers most because it is the best conductor of electricity. Some investigators claim also that a decayed tree is a better conductor than a live one.

Trees standing alone are in greatest danger of being struck, whereas one of the safest refuges from a thunderstorm is the heart of a dense forest. Picnickers caught in the woods by such a storm should stay as near the center as possible, for a dense growth of trees offers the same safety as does a thickly-built community.

Tall trees offer little protection even to small buildings, despite the common notion of country people that they offer better security than lightning rods. Trees most usually struck average in height from fifty-two to sxty-six feet. All trees are in greater danger if near bodies of water than if in dry places. Even narrow ditches or rain puddles add to their danger. A majority of those who are killed by lightning are struck while standing under trees.

There are annually struck four times as many people of outdoor occupations as people in general. This shows that we should take care to be indoors during a storm, whether in the city or country.

People caught in a thunderstorm should not collect in crowds or stand near cattle or other animals grouped together. Large aggregations of men or beasts offer much greater attractions for thunderbolts than do individuals scattered about, singly; for the material of the living body, whether that of a man or beast, is even a better conductor of electricity than the wood of trees. Thus a man or an animal leaning against a tree receives the full discharge of lightning if the latter strikes the tree. And where there is a collection of material of considerable conductivity, whether flesh or iron, the lightning is attracted the more readily.

As to the relative dangers of farm animals statistics show that there are struck more than twice as many cattle as sheep, more sheep than horses, more horses than pigs, and more pigs than mules. Farm animals are often killed in large numbers while huddling together, not only under scattered trees, but near wire fences. Such fences should be "grounded" at frequent intervals—every two or three hundred yards—by an iron wire running down the post into the ground and joined to the fence wires by staples..

Barns, sheds and warehouses are struck more often than dwellings, stores or office buildings, while churches and schools are struck the least often of all, according to the most complete statistics; but just why this is so out meteorologists are as yet unable to determine. Three times as many barns as dwellings are struck annually. The roof most often destroyed by lightning is that of wood, that of slate ranking next, and that of metal being the safest of all. This is because metal, being, of these three materials, the best conductor, scatters the electric current, which escapes before the house can be set on fire.

The use of lightning rods has fallen off in our country within the last generation, yet the question whether they are really needed comes up when the home-maker builds his first house. Professor A. J. Henry, the lightning expert, has this to say on the matter: "In large cities the use of lightning rods is not imperative owing to the prevalence of modern steel structures, and, in general, buildings with metal roofs. For buildings which stand isolated in the open country the prudent course would be to install thereon a system of protection from lightning."

It is advisable to stand back from windows or doorways during thunderstorms, since the lightning, if it strikes the house on that side, might enter at such a point of decreased resistance. But whether the window is up or down is a small matter, beyond keeping out the rain, as a powerful thunderbolt, if aimed at a window, would not be blocked from its course by a thin sheet of glass. It is further advised that we should keep away from chimneys, or fireplaces opening into chimneys. The chimney, being the tallest projection, is the probable path which lightning would take if striking an unprotected house. Another warning has been sounded by the Weather Bureau against attachnig wire clothesline to the house, whither it is very likely to lead lightning. A very dangerous position indoors is against a wall near where such a line is fastened outdoors.

J. E. Watkins.

SPRAYING TO CONTROL THE POTATO BLIGHT

Spraying potatoes is practised for two main reasons; first, to control the Colorado beetle, and secondly, to control late blight. There are other minor reasons. Experiments have shown that several solutions will destroy the Colorado bettle, but spraying should be done thoroughly All plants and all parts thereof should be well covered. In the case of a plant that has been only partially sprayed, the unsprayed portion will be eaten off by beetles very quickly. Careless spraying will leave enough of the beetles to keep up the work of destruction. One spraying carefully applied is better than several shiftlessly done. Two special applications are recommended for beetles, one when the plants are from four to six inches high, to be followed by another from one to two weeks later It may be necessary to do the spraying earlier or at shorter intervals if the attack is particularly severe.

The following solution is recommended: 8 to 10 ounces of Paris Green, 1½ to 2 pounds of arsenate of lead to 40 imperial gallons of water. Swift's arsenate of lead should be used It comes in kegs in the form of a soft paste, which readily dissolves with stirring. Paris Green is a deadly poison which does not dissolve in water and must be held in suspension by constant stirring.

This solution adheres satisfactorily to the foliage and controls the ravages of the beetle. Spraying should generally be commenced about the first of July and continued once every two weeks until harvest, using "poisoned" Bordeaux of the following composition: Four pounds of lime or more if necessary; six pounds sulphate of copper, twelve ounces of Paris Green, 40 imperial gallons water.

Spraying should not be done on windy days. It is advisable to spray early in the morning or to commence two hours before sunset, and it should be postponed in unsettled weather, but thoroughly done after a period of rain.

To prepare the Bordeaux mixture, slake a quantity of quicklime in one or more barrels and fill them with the paste almost to the top, keeping the lime covered with water, or the lime surface will dry up, become lumpy and interfere with straining. Prepare a "stock solution" of blue stone in such concentration that when using one gallon of (stirred) mixture, one pound of the chemical in solution is contained therein. To do this dissolve two pounds of blue stone in two gallons of hot water, and empty the two gallons into a barrel; repeat the process until you have one or two barrels full of the "stock solution." Then if you take for use one gallon of "stock solution" you will have one pound of copper sulphate.

To make forty gallons of spray you will require six pounds of copper sulphate with an excess of lime, i.e., an amount sufficient to prevent injury to the leaves. Therefore, have a barrel containing some 33 gallons of water, and add to this six gallons of the sulphate of copper "stock solution," (or six pounds of dissolved chemical). Next add a quantity of lime paste and stir well until dissolved. When dissolved use a testing fluid to ascertain excess or deficiency of lime. The test solution is as follows:

One-half ounce potassium ferrocyauide (poison) dissolved in one-half pint of water. Fill this solution into a dropping bottle. Having added and dissolved the lime in the copper sulphate solution, as described above, stir well the contents of the barrel and allow one minute to settle, then drop a few drops of the "test solution" into it. If these on striking the surface color the liquid brownish, add more lime, stir until dissolved and test again; if the mixture does not change color, the solution contains the proper amount of lime. Finally, add to each 40 gallons of spray the proper quantity of Paris Green, strain through brass wire cloth strainer into pump and solution is eady for spraying. Replenish "stock solution" as required.

HORTICULTURE

CO-OPERATION IN GROWING AND MARKETING APPLES IN CANADA

In dealing with the subject of co-operation in the growing and marketing of apples in Canada it will be necessary, in order to discuss the matter intelligently, to discriminate to some extent between the many forms of so-called co-operation and successful co-operation.

It is not my intention here to attack the apple dealers, nor do I join with those who declare that the ultimate goal of co-operation is the complete elimination of the middleman. Nothing in my judgment could be further from the true spirit of co-operation, and it must be admitted that a great deal of pioneer work in the past in the creation of markets should be credited to the dealers or middlemen.

Here, too, we must discriminate between the reputable business man who in the past made heavy investments of his own money in what he considered a legitimate business on the one side, and the army of undesirables known as itinerant buyers on the other, who had everything to gain and nothing to lose. Growers need have no worry about middlemen, as, under co-operation perfected along proper lines and applied intelligently, the undesirable dealers will work out automatically, and the obstructions between the producer and consumer will be reduced to a minimum.

But there always will be a place for the reputable middleman; he is as sure to be with us as the tax collector. Our butcher and our baker are middlemen, and it matters little to the grower when his product is ready to offer for sale on a competitive market, who the buyer is, so long as he receives a fair price for the goods. The keen business man, too, who has worked up large business connections, is in the very best position to place orders and create new markets, and perhaps his efforts may become a strong factor in securing successful results in what might have been started in a co-operative way.

Aims of Co-operation

Now, what are the real aims of co-operation in the apple business? First, to make it possible for the small growers to place their fruit in the best markets by the grouping of shipments. Second, to reduce the cost of production and packing by purchasing collectively supplies for orchard work and by centralizing the management of packing and shipment. Third, to create a friendly rivalry between growers so that a maximum percentage of high-class fruit will be produced. Fourth, that being in a position to offer for sale large quantities of uniformly packed fruit, the best buyers will be attracted. Firth, co-operation is a security for the consumer that he is getting what he buys, inasmuch as the manager, being an uninterested party, would pack according to the rules of the association.

It has been said that "It is not well that man should pack his own apples." It was once recommended that where two growers Smith and Jones were living side by side that, when packing time came, Smith should pack Jones' apples and Jones in turn should pack Smith's. We never did get quite this far in Canada, as the co-operative plan stepped in and the packing was centralized under expert management.

Surplus of Fruit

The apple industry of Canada originated in the planting of small orchards by the settlers, the product of which was intended for home use. Occasionally, however, large orchards were planted here and there in Ontario and a still larger number of such in Nova Scotia, no doubt intended for commercial purposes. Soon these orchards produced a surplus over local demands, and it was then that here and there an enterprising dealer took a chance and began making small shipments to Europe. Many of the shipments showed large profits and the trade grew by leaps and bounds. The dealers for some years controlled the shipping of fruit, assuming that by divine right that was their part of the game. The growers seemed to think so, too, and submissively took what was given them.

Soon, however, the trade passed into the hands of the itinerant buyers, who sprang up all over the country; they would make their appearance when the demand was good, but in the case of a full-crop season the unfortunate grower would look in vain for a buyer and thousands of barrels of good fruit remained on the trees. Then it was that the necessity of some move on the part of the growers presented itself, and, in 1896, when the first huge glut occurred, the first nibble at co-operative shipping was attempted. A number of growers mutually agreed to group their small lots together making up carloads for export. The fruit was packed by the growers whose names were branded on the packages. A man schooled in the art of shipping looked after the shipments at a fixed sum per barrel. In some cases little or nothing came back to the growers.

Packing Law

One year under this plan seemed to satisfy the growers that they were never born to be shippers, and that the part they were to play in the apple game was to plant the trees, board the apple gangs, and draw the fruit to the shipping stations. In the last years of the '90's the Canadian apple trade that had been gradually running into disrepute reached the climax. Then came the Fruit-Marks Act, or Packing Law, and the co-operative movement. The operation of the law soon drove the unscrupulous packers out of business, and the growers were confronted with the necessity of finding some means of marketing their fruit. The co-operative plan seemed to be the best thing in sight and scores of associations sprang up all over the fruit-growing districts. The two main principals governing these associations were: First, the association brand was to be placed on all packages, and the packing was to be under the supervision of a manager; second, a condition was inserted in the by-laws making it obligatory on the part of all members to spray and care for their orchards.

Co-opeation like all new movements was bound to strike some snags and many of the weaker associations that did not follow business methods, or were too small to support a proper management, went down after a few seasons' trial, but the principle was sound, and, with the aid of the packing law, it can be said to have redeemed the apple industry of Canada.

Co-operation in Nova Scotia

Perhaps in the Annapolis Valley, N. S., is shown the most striking example of the co-operative movement in Canada. This valley less than one hundred miles in length has some fifty local associations and is dotted with storehouses—some of the associations having several. These buildings are frost proof, usually 100 feet by 40 feet in size, having a basement the full size of the building. To these buildings the fruit is hauled and the work of packing for shipment is supervised by expert packers.

While the co-operative plan thus far carried out completely revolutionized the handling of apples in Nova Scotia, yet it was shown that the methods were still faulty, inasmuch as the different associations developed a keen competition in selling their fruit. Some, in order to make a sale, would undersell their competitors, and it was a common occurrence to see, in the markets of the Northwest, Nova Scotia apples of same quality offered for sale side by side in which the purchasing price varied 50 cents to $1.00 a barrel. Neither was there any control o fthe distribution of shipments, the result being that while some markets were oversupplied others were bare of fruit.

This state of affairs plainly showed the necessity of some further move on the part of the growers, and as a result there came into being what is known as the "United Frut Companies of Nova Scotia Limited." The membership of this company is composed of the local associations, and while the local managers still look after the packing, all sales and general business is carried on through the central association, with offices located at a central point. Of course it would be too much to expect that all the smaller associations would rush to the central one, but it has a very large following and its operation has shown that there remains but little more to be done to perfect the plan of co-operation in order to reach the highest aims of the apple growers.

The Buying of Supplies

In addition to looking after the marketing end, the central association has taken up the matter of supplies for the growers. The many storehouses are utilized for the storing of same, which comprise everything that is necessary for the care of the orchard. Lately, however, the association has gone a little further in the way of supplies, which is shown by the following list of supplies for the last year:

Spray Material	$23,312
Nails, Pulp Head and General Merchandise	17,118
Fertilizer	90,241
Insurance Premiums	2,149
Flour and Feed	91,689
Seed Oats and Seeds	19,133

The company for several years have had a competent man placed in the European markets to look after shipments and observe conditions surrounding the marketing end of the apple business. This has proved of great value to the growers, who generally know but little of the many troubles met by their fruit while in transit and after being landed.

To show how expenses may be minimized by central organization, the salaries and expenses of the management of the central association are covered by a sum amounting to less than 5 cents per barrel. It may be that the growers are looking forward to a time when co-operation will form a complete chain between producer and consumer, but there may be a danger of carrying it too far. Perhaps co-operation will have served its purpose when it has encouraged and aided the growers in producing fruit of the best quality at a minimum cost, packing it honestly under the best methods, and offering for sale, free from any handicap, to world-wide competition through the natural channels of trade. The apple business at this stage would enter into another phase and it would then be up to the consumer to look after his end of the problem.

The Social Side of Co-operation

Where co-operation has not been a success, the troubles are easily traced. The chief one being the lack of loyalty on the part of the members. Then every association has its knockers. Jealousies often creep in, competent managers are hard to secure, but when the whole matter is summed up it can be said without question that the co-operation in the handling of apples in Canada has been a great success.

So absorbed are we in the mighty dollar, we are apt to overlook the good that is brought about by co-operation in a social way. The co-operative spirit is a sure cure for selfishness, an evil that apple growers possess as well as other classes. It is a cure for the fellow who, when he thinks he has discovered something to his advantage, hides it carefully under his hat. The true co-operative spirit carried out along proper lines makes a community like one big family striving to make the best out of life and its activities, makes us better men and women, and makes for a higher standard of citizenship.—P. J. Carey, Dominion Fruit Branch, Ottawa, Canada, in American Fruit Grower.

PROTECTING FRUIT TREES AGAINST BORERS AND RABBITS

Such parasites or "free boarders" as fruit-tree borers and rabbits may cause great damage to both young and old trees if not carefully guarded against.

Grade D asphaltum is perhaps the best protector against those prowling submarines, the root or crown borers.

Remove the soil down to the main roots and apply the asphalt, while warm, with a brush, covering with a thick coat to at least six inches above the ground. By extending this coat up to the first branches on young trees, the flat-headed borers and also rabbits will be held at bay.

If newly planted trees are protected from sunburn by shading or by whitewashing there will be little danger from the flat-headed borers, as

they rarely attack trees that are healthy.

Wooden veneer or screen wire wrappers which may be thrust into the ground for about two or three inches are reliable potectors against borers. If these wrappers extend up to the branches they form a true safeguard against trunk injury from both borers and rabbits.

If borers are already in the trees when asphaltum is applied they will certainly perish if the asphalting has been well done, as they will be unable to come out and go through their later period of development, and therefore, they can never become full-grown insects to lay more eggs.

Do not use tar of any kind as a surface covering, as the trees are very apt to be killed. The same is true of axle grease or anything containing creosote. However, washes containing vile-smelling materials like asafetida may be safely used as repellants against rabbits.

STUDYING POLLINATION

California, with her enormous prune industry, has for the past three years conducted experiments that seek to solve some pollination problems. The resulting bulletin, No. 274, from the College of Agriculture, Berkeley, Call., is worthy the perusal of every horticulturist.

Most interesting are the results of a special experiment upon two pairs of adjoining French and Imperial prune trees which were inclosed in large tents of mosquito bar before the blossoms opened. Into one of these tents a hive of honey bees was introduced and there kept throughout the blossoming period. Into the other tent no insect of any sort was admitted during the blossoming period.

The table of percentages of fruit that actually matured shows that, while the French prune responded almost excessively to the pollenization of the bees, the Imperial prune for some unknown reason fell below the average orchard set, though quite beyond the tree from which all insects had been excluded.

Further experiments are promised along this line in an endeavor to solve the puzzle of the poor set of fruit on this Imperial prune tree.

The bulletin is very suggestive for fruit farmers of all sections, and especially interesting is the project of the prune growers to hire hives of bees from men having large swarms and to place them in the orchards during the blossoming period. This plan is already in use in the orange groves of Southern California.

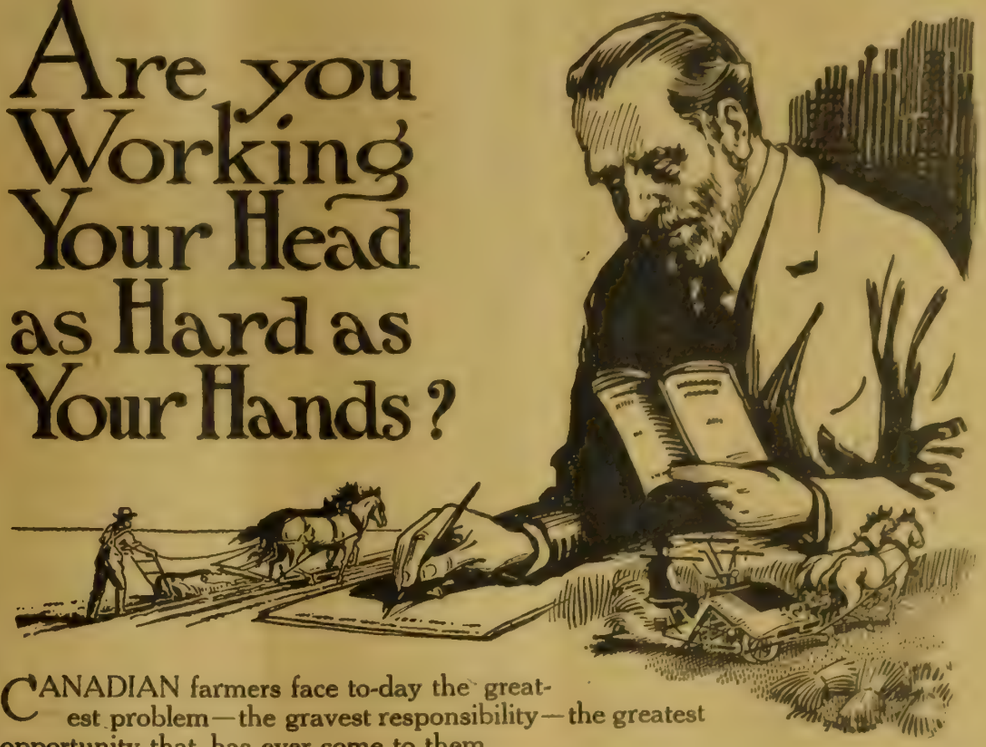
IMPORTANCE OF ROOT HAIRS

The root system of a plant is divided and sub-divided into many fine rootlets. There arise from the surfaces of all growing rootlets, very small, simple structures, the root hairs. Practically all the water and mineral nutrients are taken in from the soil through these root hairs. The absorbing surface of a root bearing hairs is from five to ten times that of a hairless root of equal size. The importance of root hairs may be judged from the above statements.

Root hairs are being formed anew constantly. The life of any individual hair is very short, as a rule. They are extremely sensitive to air and soil conditions. They collapse immediately on exposure to air. Cold soil and very wet soil retard their development.

Usually, when a seedling is transplanted, the root hairs immediately die. Wilting of the plant results and it does not revive until new root hairs are formed. In order to compensate for the destruction of root hairs in seedling transplanting, it is customary to cut back the water-losing organs, the leaves. In transplanting seedlings, pains should be taken to preserve the finer, young, growing, and root-hair producing rootlets.—W. W. Robbins.

Are you Working Your Head as Hard as Your Hands?



CANADIAN farmers face to-day the greatest problem—the gravest responsibility—the greatest opportunity that has ever come to them.

Three years of fighting has made food the one vital factor in the struggle. If the Entente Armies and the workers behind them can be kept well fed, victory is certain. To this "if" the farmer alone can supply the answer, "yes."

The problem is enormous, expressed in hundreds of millions of bushels of grains. The answer must come in the few hundred or even few score extra bushels which each individual farmer can manage to grow. Head work is needed to make the utmost of the limited supply of labor. Only be careful planning and better methods can the increases so urgently needed be made.

Every bushel added to the food supply available for 1918 will be a definite service to the Empire, and at the same time will bring its own reward to the grower—for never in this generation have crops brought such returns. Never has there been such a patriotic incentive to make big money, for

MEANS OF CONTROLLING CHERRY AND PEAR TREE SLUGS

The slimy looking larvae or "slugs" that eat the surface off the leaves of cherry and pear trees during July and August are easily killed. If there is no fruit on the trees, the best way is to spray the trees with arsenate of lead in the proportion of 1 pound of the powder, or 2 pounds of the paste, to each 50 gallons of water. A fine spray is best, and should be applied so as to cover the upper surface of the leaves, where most of the feeding is done.

In case there is fruit on the trees you may use white hellebore, 1 ounce to 3 gallons of water. This will kill the slugs and do no harm to people who eat the fruit.

The same results may be secured by spraying with a strong tobacco decoction, such as Black Leaf 40, 1 part in 800 parts of water.

A thoro dusting with slacked lime, ashes or fine road dust will usually be successful in removing the slugs from the leaves.—C P. Gillette, Colorado Agricultural College.

DAIRYING.

USE OF DAIRY BY-PRODUCTS

Contrary to popular opinion, skim, or separated milk is a very valuable feeding material, containing, as it does, all those nutritive constituents found in the whole new milk, with the single exception of the fat.

Now, butter is one of the most expensive forms of fat available to purchase, and consequently a very considerable economy can be effected by the use of some cheap form of fat and the separated milk, in place of whole new milk, whether it be in the household or in feeding stock on the holding

Apart from this, it is quite easy to produce cheese of useful feeding value, such as Caerphilly and Dorset Blue, from milk which has had a large proportion of its fat removed.

It is obviously extravagant and wasteful to feed butter fat to calves. They will do quite as well, as has already been demonstrated, on fat substitutes and cream equivalent used in conjunction with separated milk, as they will on the whole new milk.

Pigs, again, are never more profitable than when cheap dairy by-products in the form of separated milk, butter milk, or whey from the dairy are available for feeding, in conjunction with those concentrated foods that are produced on the holding, or can be purchased at a reasonable figure.

In commercial industries the value of these dairy by-products has long been recognised, unfortunately, more often abroad than in our own country. For example, separated milk contains a fair proportion of casein, which will coagulate and form a curd with the addition of rennet or dilute acid, and we have already seen this curd may be used for the manufacture of cheese. Now, however, chemists have discovered a variety of means whereby casein can be profitably utilised. For example, it has been found that, on the addition of formaldehyde, the casein may be thrown out into a soluble mass, in which condition it may be used for a number of purposes, as, for example, in the manufacture of phonagraphic plates, billiard balls, shoe polish, ointments, wood-cement, washable drawing paper, and water-proofing paper. Its plastic and adhesive nature has also been rendered very valuable for the manufacture of paints, washes, and enamels, and especially in the case of cold-water paint, casein cement, "marble lime," enamel paint, and calsomine wash.

Apart from these commercial uses is the manufacture of patent foods, in which the actual feeding value of casein has been put to a very good use, the curd being dried and reduced as Sanatogen, which contains as much as 95 per cent. of casein. Plasmon, again, contains 75 to 80 per cent., and Dr. Regal's Milk Albumen, Lacterine, and Calactogen, and many other casein foods, consist of dried casein mixed with starchy materials, such as flour, rice, arrowroot, tapioca, etc.

The actual cost of the production of the dried casein in these foods is at the rate of about 6d. per lb. Another use for casein is that in the manufacture of baking powders, many of which comprise casein phosphorates, made by compounding casein with lime phosphorate and water, or by simply mixing the casein with bi-carbonate of soda. AGROSTIS.

THE COW'S UDDER

In these days when dairy cows are selling for big prices, one has to be pretty careful in buying. Assuming that a buyer gives a good figure a piece for a bunch of good-looking in-calf heifers, he never knows what his luck is going to be when they calve down; some may have promising bags, while others are of the "beefy" type, and have to be passed on for feeding.

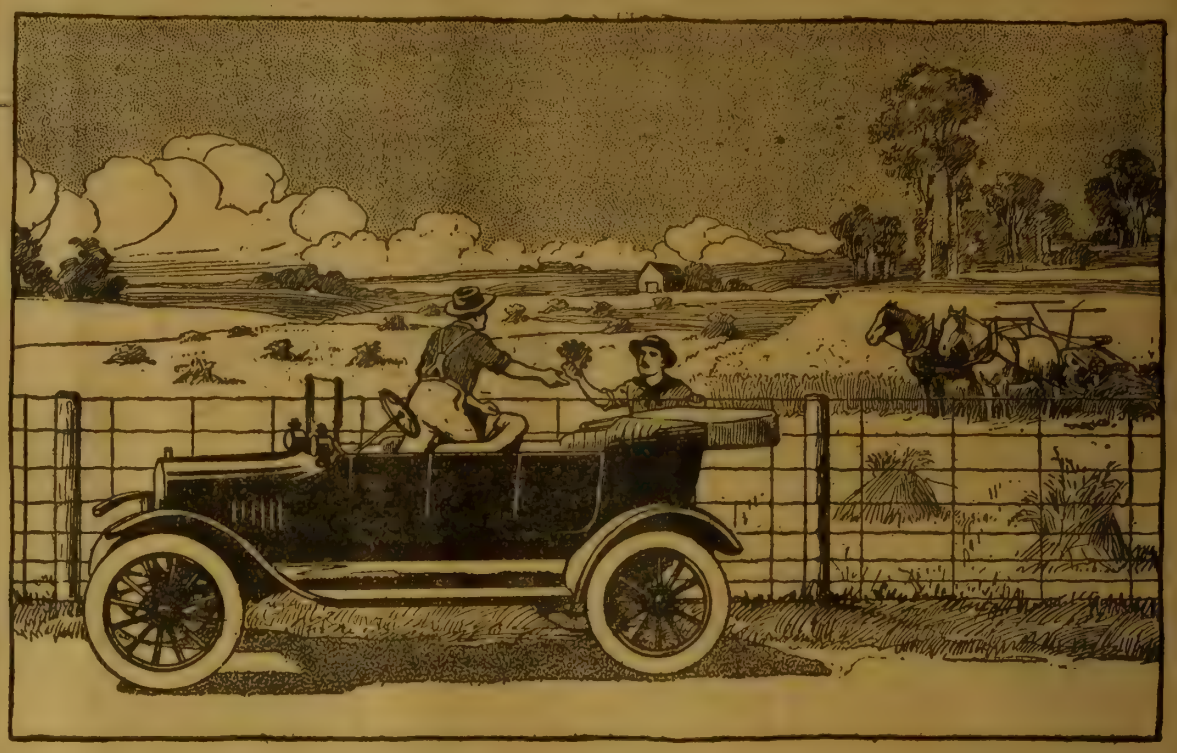
When buying newly calved cows at these high prices, much depends on the quality and condition of the udder, as a cow without a good udder is something like a horse with a defective foot. It is quite certain that a cow is worthless as a milker without an udder, but let her be ever so deficient in other points so long as the udder is conspicuous, or exceptionally prominent, she will be accepted with open arms.

The Question of the Udder

Although by no means an invariable guide to the capabilities or perfection of the cow, it is the quantity of milk likely to be given that the udder indicates, and neither the size nor the form of it divulges the quality of the milk given. But quantity is also a leading point, and the cow with the largest udder is generally the highest priced whenever she changes hands; hence the demand for large-uddered cows. Some have studied the production of cows that will yield excessive milk and the highest class of butter, but as yet little has been heard of breeding for great udders. No doubt some will have thought of it, and we may hear more of it in time.

Dealers are intimately acquainted with the extra profits attached to a huge udder. Their utmost endeavours are directed to their production

If they get a cow that has naturally a fine bag they run her for all she is worth, and if the size is deficient it is extended to its utmost capacity by non-milking for days and nights before the cow is put on the market. This practice is most objectionable, both to the cows and buyers. It is a deception which most surely borders



Real Daylight Saving

In the harvest time every hour between daylight and dark is worth money to the busy farmer.

You get an early start in the morning intending to do a big day's work, but the binder, mower or other implement breaks down and you must go to town for the repairs. If you have a Ford you are soon away and its speed clips two hours off the former three-hour journey there and back.

Count up the extra half days that a Ford will save you

during the rush of seeding, haying and harvest. You will find that the Ford will save you a week or more of valuable time on your necessary trips alone.

Many times you will want to take some produce along with you. Then your staunch Ford is ready to carry a load of 1000 pounds. How handy this would be?

Once you own a Ford and find out the many ways you can use it for business and pleasure you will wonder how you managed without it.

The Ford is an economical investment, and a necessity on every farm.

on fraud, and is highly misleading. Thus, apart from mere appearance, the udder should be better understood by all who deal in cows.

There are Various Forms of Udders

But as long as it is huge, the correct type is often disregarded. There are udders which seem partially detached, and are not well collected round the usual position. This is often seen in old cows, and may be taken as an indication of age. Others have udders almost bottle shaped. The udder is long and narrow, and neither extends in front nor sticks out behind. This is a bad type, and the udder much to be preferred is a deep, wide, long, almost square-bottomed one, going bulky along the belly to a considerable distance, and filling up behind. Given a chance, excessive milkers. One that shows a great deal of udder behind the back legs and little in front is fourth rate. The teats, too, are indications of milk or the reverse. In some cows the four may be seen almost as close together as one's fingers, clustered and drooped. This is bad form, and such cows should not be bred from. Their type is not wanted.

The Teats Should be Wide Apart

The hind ones are usually larger than the front ones. This is no fault. Some cows have large teats, others small; but the size of the teat has little to do with the milk supply. Indeed, it has nothing, as some of the smallest-teated cows of the Ayrshire breed are tremendous milkers. The desire for big teats is a matter of convenience. Milkers all like a handful of teat, and little ones are apt to lead to the cow not being properly milked. But a good milker can manage the small ones nicely, and make no complaints.

Most cows with their first calves have small teats, but in time, with the constant drawing either in sucking or milking, the teat lengthens, and in the end some cows have large teats that are quite out of proportion. It is the milking that keeps them going, too, as when a teat is blind and not milked, the other three will be long and plump, while the disused one will be small and shrunken. Teats in all forms are, however, most important accompaniments to the udder, and, apart from a preference for size, whether they are all in working order or not is of the greatest importance. The one thing to avoid, above all matters in teats, is blindness. This is a term applied to a teat from which milk cannot be extracted. It may have been caused from careless milking or some ailment, but as a rule the blind teat is a result of careless treatment. It detracts pounds from the value of the cow as a milker, and many will not have such at any price. Three-teated cows will not give so much milk as if the four were going; but the quantity will not be a great deal less. Buy them at a price when newly calved, and at the end of milking convert them into beef or sell them for that purpose. The importance is shown by the fact that at all sales of high-class cows are on show, one of the first guarantees is that they are sound in their quarters, and this applies to their teats.

When Buying an In-Calver.

When a cow is bought before she calves, or when dry, her teats cannot be proved by drawing milk out of each one, as should invariably be done if milk is in them. Look at an old hand trying the cows in the market. He will go round every one that takes his fancy, and test their teats. If one fails the cow is shunned. If two teats are blind, she is worthless as a milker. While trying the teats the hands should be pressed hard into the udder. If the bag is hard and fleshy, the milk accommodation is pretty sure to be deficient; but if the udder is soft and pliable, there is room for milk.

The fleshy bag and the former we often find misleading, as it is always bulky, while the milky bag shrinks much when all the milk has been extracted, and this is the sort undoubtedly. Much can be learned at the market when a lot of cows are there, but a close observance at home and a thorough knowledge of every inch of the udder of the cow that is the best milker will help greatly to keep one from making deplorable mistakes.

"There aren't many engines I'd trust him with, but the Alpha is so simple that I know he can't go wrong."

Isn't that the kind of engine you want around *your* place—an engine that is as steady and dependable as the best horse you've got?

The Alpha doesn't have to be "tuned up" every time you want to run it. It contains no electric batteries to weaken and give trouble—no complicated parts to get out of order. To start it you simply oil it, turn on the fuel and give the flywheel a pull.

You need a gas engine and it pays to buy a good one. There are definite reasons why the Alpha is best.

Alpha Gas Engines are made in eleven sizes, 2 to 28 H. P., and each size is furnished in stationary, semi-portable, or portable style, with hopper or tank-cooled cylinder.

50,000 BRANCHES AND LOCAL AGENCIES THE WORLD OVER

ARE GOOD COWS MIS-JUDGED?

Recently three cows that stood side by side were tested for nine consecutive milkings. The first cow had an average test of 3.7 per cent of fat, the maximum and minimum tests being 2.9 and 5.5.

The second cow had an average for the nine tests of 4.2 with maximum and minimum tests of 2.4 and 5.4. The average test for the third cow was 2.6, with extremes of 2.0 and 4.0

Hence it is evident that the laudable desire to know what a certain cow's milk tests for fat may be defeated entirely if only one sample is run through the machine.

In the light of the examples given above, as well as of hundreds of other instances on record, it is safe to conclude that a fair method is to test a composite sample of five or six milkings taken at intervals when the cow is in normal condition. This plan has given good results in the cow testing work of the dairy division, Ottawa. Write for full particulars, so that your good cows may not be misjudged on an isolated test. C. F. W.

HE KNOWS

"From my herd of eighteen cows I sold four hundred and twelve dollars worth of cream in June. I think I am doing very well"—writes a farmer when applying to the Dairy Division, Ottawa, for a further supply of daily milk record forms and a herd record book.

HE KNOWS just what each cow is doing, if she gives less than say thirty-six pounds of milk a day, he hunts round to find out why she dropped off in her yield and he tries immediately to prevent any repetition of unusual shrinkage.

He also tests once a month, a composite sample of six milkings so that again HE KNOWS which cows make the best returns in cream. After a few tests he sees that Daisy gives 4.5 milk and Buttercup gives onyl 3.6. He does not believe in a rough and ready, haphazard, easy-going "guess" as to how much fat the whole herd produces in a year; HE KNOWS from his milk record sheets and herd record book which cows are making money for him. Recently he sold some of his poorest because they did not make enough. Rather a good plan, isn't it? When you decide to follow such a sensible example, write for forms, they are free, and your letter need not even be stamped. C. F. W.

Far more effective than Sticky Fly Catchers. Clean to handle. Sold by Druggists and Grocers everywhere.

More Money for the Farmer

WHEN live stock is tormented by vermin, lice, mites or flies, it cannot be profitable. You can prevent this annoyance and have more profitable stock by using Creonoid. Think this over. It means money for you.

CREONOID

Lice Destroyer and Cow Spray

Creonoid stands alone as a lice killer and cattle spray. Economical too, because it is so strong that a little goes very far. Give your horses and cattle a fine, long distance spraying, so that they get the vapor. It will make them clean and vermin free. Put some Creonoid in the hennery and piggery. The use of Creonoid means better stock, more eggs, more good porkers, more milk. Try some now.

NEW BRUNSWICK AS A SHEEP COUNTRY .

One often hears from an outsider the expression, "What a splendid sheep country New Brunswick would make." This is very true and we all know that it would, but have not realized it, and our sheep population has declined very rapidly. Often we get in a rut like this and pursue the even tenor of our ways oblivious to out natural advantages. However, there was a time when wool and lamb prices were very low and the sheep men became disgusted, and dropped out of the business, but now and for a long time to come, no one need fear any serious drop in prices. It is a well known fact that meat consumption is increasing and meat producing animals are decreasing in numbers the world over. Let us analyse the various sheep countries of the world and see what they have to offer. The Australian supply of mutton and wool is a questionable commodity. The country is subject to drought and this is sure to effect the sheep crop. Then they are situated a long way from the principle wool and mutton markets of the world, viz: London, Boston and New York. This disadvantage offsets many of the natural advantages in favor of Australia, as a sheep breeding country. Argentine is probably the most important exporting country in the world, that is to say they export a bigger per cent of their product than is the case of any other country. Sheep and beef are the two important classes of stock kept by the natives of Argentine. Poor railway and shipping facilities along with droughts limits the amount of mutton export from Argentine. Along with these there is a growing movement towards mixed farming.

In point of numbers probably the United States might be considered the meat country of the world. Their population is however increasing very rapidly and their export trade in meat, once the greatest in the world, has rapidly decreased. Home consumption accounts for this. Now they are importers. Next to Great Britain they import more wool and mutton than any country in the world.

The same applies to dairy products, the United States is an importer. South Africa has developed into a sheep country and has the natural advantages necessary for mutton production, but the climate is not the best for producing wool.

The European countries such as France, England, Scotland, Germany, Austria Hungary and Russia in normal times, produce a good supply of mutton and wool. Of course they do not produce enough for home consumption. During the last three years this production has very materially decreased. Their breeding stock has been depleted due to war demands and it is very probable that this stock will be still further drawn upon for food. Coming closer home few of us but are familiar with conditions in Canada. In 1910 we had 2,598,470 head of sheep. In 1914 the number had decreased to 2,058,045, that is a decrease of over half a million in five years. In the year 1910 the Province of New Brunswick had 203,620 sheep; in 1914 this number had decreased to 121,739 sheep, that is a decrease of about 40% in five years. In 1914 Canada imported 5,610,812 pounds of mutton and lamb, and 7,252,119 pounds of wool. In the same year Canada exported 65,167 pounds of mutton and 2,841,184 pounds of wool. In the same year Canada exported about 20,500 head of live lambs and sheep. This is the situation in Canada and it is a very good index to the situation in the United States. To sum it up properly, we have been going backwards

TRUE ECONOMY

DEMANDS THE USE OF MORE

PURITY FLOUR

There is more actual food value in ONE POUND OF PURITY FLOUR than there is in One Pound of Beef, One Pound of Potatoes and One Pound of Milk COMBINED.

The truly economical housewife must take advantage of this great strength in PURITY FLOUR over other food substances by serving more frequently the delicious bread and rolls, toothsome, dainty cakes and crisp, mouth-melting pastry which are among the possibilities of this perfectly milled product of the world-famous Western Canada wheat.

for eight or ten years, and have finally arrived at the stage where we import more than we export.

Why New Brunswick Farmers Should Stock Up

One might say that there is an unlimited market for mutton lambs at home and abroad. During the next few years the United States can easily take the entire product of Canada. The same thing applies to Great Britain or France. In the Spring of 1917 wool sold for 60c and 65c per pound in New Brunswick. Next year it won't be any lower and no doubt will reach the 70c mark. Lambs are easily worth $10.00 this fall.

People engaged in the sheep business haven't suffered to the same extent from high priced labor as have other branches of farming. The labor involved in sheep production comes at a time when there is very little other work to be looked after. The lambing, shearing and dipping season covers the big end of the labor involved. Throughout the summer little if any real labor is required. The feed bill is not very large—mixed timothy and clover hay or preferably pure clover hay supplemented with Swede turnips, with a handful of oats is the best winter rations and incidently a cheap one. Hay prices have been low during the last two years and farmers can profitably winter more sheep instead of selling hay. Summing up, one might say that sheep raising offers one of the best investments obtainable for:—

1. Mutton, lamb and wood prices are good.
2. There is very little labor involved in sheep farming.
3. It is a most profitable way of marketing out hay crop.
4. We have in New Brunswick good upland pasture and plenty of water.
5. We have easy access to the best markets in the world, Great Britain and the United States.
6. The investment involved is a small and the turnover is big and quick. The wool crop is marketed in the spring when very little money is coming in to the farmer.

What the Department of Agriculture Has Done and is Doing

Probably one of the greatest curses to the sheep industry has been the dog nuisance. The old dog law has been amended so that it is now up to the sheep breeder of the district to say whether the dog shall be controlled or not. It depenls on the enterprise of the sheep breeder whether the dog shall be controlled or not. It depends on the enterprise of the sheep breeder whether he has dog protection or not. The Live Stock Division of the Department of Agriculture has been acting as an exchange between breeders and purchasers. Breeders who have stock for sale communicate with us, likewise those desirous of purchasing stock, and we have been able to give material assistance to the purchasers re the location of stock and prices.

A great number of people have taken advantage of this, in fact so many that our local supply of flock headers and pure bred ewes is pretty nearly exhausted. If local breeders cannot supply the demand we shall import from the upper Provinces. In this latter case, people deposit a sum of money with the Department of Agriculture, sufficient to cover purchose price and freight charges. The Department furnishes, free of charge, a man to make the selection. To those people who are stocking up with grade ewes we give similar assistance.

In closing I would say "It is a good time to stock up with sheep." Mr. Farmer get busy. If you haven't any sheep you should get some. If you haven't any available stock in your district, write to us. Use the Department. We are here to serve the farmers.

Thomas Hetherington,
Superintendent for Livestock.

Always the Same

"Beaver" Flour is as uniform in quality as a minted five dollar gold piece.
Its proportions are as accurately fixed, and as scientifically determined.
The wheats used in milling "Beaver" Flour are analyzed—and the percentages of gluten, starch etc. are found by chemical tests.

We know—

from years and years of experience—just how much western spring wheat to add to the choicest Ontario winter wheat—to obtain the desired strength.

BEAVER FLOUR

Equally good for Bread and Pastry. *Milled of Blended Wheat.*

This is why "Beaver" Flour always gives good results—why it requires less shortening—why everything you make with it has a flavour that you cannot get with western spring wheat flours. Try "Beaver" Flour yourself for both Pastry and Bread—you'll find it equally good for either, and best for both. Remember, to insist on having "Beaver" Flour—the original blended wheat flour.

DEALERS—write for prices on Feed, Coarse Grains and Cereals.

THE T. H. TAYLOR CO. LIMITED, - - CHATHAM, Ont. 201

CARE OF EWES AT WEANING TIME

Lambs kept for breeding stock should be weaned when from four to five months of age. The lambs intended for market, on the other hand, should attain marketable weight before they are five months of age and should be weaned at the time they are sold.

Lambs at weaning time should be kept for four or five days at least on the old pasture, as they do not fret as much as in a strange place. The ewes should be removed to another pasture as far away as possible from the lambs. If the feed on this pasture be a little scant, so much the better, for this will help check the milk flow. The ewes and lambs should not be turned in together again, for a large amount of milk from a ewe that has not been suckled for two or three days is liable to cause digestive disturbances in the lamb.

At weaning time the ability of an ewe to produce a good lamb often is ruined because the necessary care is not taken to see that she is dried off properly. A little care at this time will be well repaid. Two or three days after the separation the ewes should be milked out. All of the milk need not be drawn from the udder, but enough should be taken to leave the udder soft and pliable. Mark with colored chalk ewes needing no further attention. In about three days the ewes should be milked out again and the drys marked. Further attention should be given four or five days later to those not dry. No efforts should be spared to maintain every breeding animal in a sound and useful condition.

PULVERIZED LIMESTONE

SWEETENS THE LAND AND PRODUCES HEAVY CROPS

The demand last season for our "Clairmont" Brand Pulverized Limestone was so heavy we were unable to fill a great many orders. We expect a very heavy business for 1918 and would advise all booking now and getting their supply early. Our Limestone is showing wonderful results.

THE HORSE

TEAM OF HORSES PULL ON THEIR BITS

Is there any way of breaking horses from pulling on the bits? I have a team of horses that the further they go and the heavier the lead the harder they pull on the bits. They are becoming impossible to drive. Wagon work is the only work I have for them. Is there any bit that will hold them without cutting their mouths?—H. F. C.

Ans.:—First see that there is no irritation from the teeth that causes the horses to set themselves on the bit and pull until they numb their mouths to pain. Sharp teeth that cut the inner surfaces of the mouth are frequent causes of pulling.

The inquirer does not state how the horses carry their heads when pulling, whether on their chests or with their noses stuck out. Probably in either case they manage to get the bit back against their grinders and the driver is set to pull against these instead of the bars of the mouth, where the bit should be. It is true that some horses can pull very hard even by the bars of their mouths, but that is nothing to what they can do when they have succeeded in getting the bit far up in their mouths against their cheeks or grinders.

First try the simplest method that still leaves the horses at liberty to exert full power on a load. Use large, plain, bar bits, the bigger the better, and buckle a noseband immediately above them so that the bit is kept down where it belongs and not allowed to go up or back in the mouth. The correct position for the bit on a pulling horse is about an inch above the tush, not up in the corners of the mouth. As these horses are not runaways or bolters, it is not necessary to buckle the strap very tight to begin with, as this may cause considerable discomfort. If this plan succeeds, get wide straps and keep them soft.

Overchecks are objectionable on a draft team if put on tightly enough for correction, especially on rough ground or for a hard pull. But if used on a separate bit, especially with a noseband, they will keep a horse from hogging the bit by getting his nose down. With very tough-mouthed horses a ring martingale on the outside rein will pull downwards on the bars of the horse's mouth in the contrary direction and give a powerful control beyond the power of any but a very few horses to defeat. If the horses simply go heads in the air and let the bits slip back off the bars of their mouths, a martingale may be all that is needed. It should be only tight enough to draw down a couple of inches lower than the mouth of the horse when in proper condition.

It is essential with any of these rings to remember that pulling and hauling will cause the horses to act with great severity, the thing that the horse has tried to avoid by getting the bit out of position. To handle the reins roughly under such circumstances is to drive a high-strung horse to balk. Many horses have come to depend on a heavy pull on the bit when they are making the greatest strain on the traces.

Never be discouraged with a pair of pullers. Either their teeth are wrong or the bitting is incorrect. Study to bring the horse's head to a correct position when working, which will usually be about the unstrained position in which he stands when not interfered with in his stall. If he throws his head very much out of line up or down there is something wrong.

Always use one bit for the check and another for the reins, whether it is an over or side check, so that the driving bit may remain down on the bars of the mouth. An extra bit with a side check makes some pullers perfectly happy, as they imagine they are still pulling on the line, while they are really pulling at their own cruppers. I have had horses that kept this illusion all the years they lived; they could be guided and stopped with a two-ounce pull.

A puller should never be confounded with a bolter, which gets into a dangerous panic and cannot be controlled because he has no control of himself. Pullers merely need regulation.—L. OGILVY.

COOD WASH FOR SORE SHOULDERS OF FARM HORSES

In selecting a draft horse the shoulders should be given careful attention. A good slope makes the best collar-bed. Straight shoulders with thick withers are most susceptible to injury. If the shoulder is straight, the force of the pull is thrown on the point and not evenly distributed.

A cheap, ill-fitting collar is a poor investment. The best way to secure a good fit is to take the horse to an expert harness maker, where the proper size can be obtained. Or measurements may be taken from which a collar can be made to order. If the horse has been idle through the winter and has taken on surplus flesh allowance should be made for the si e needed when the horse reaches its normal weight. When the collar is in the proper position there should be room to allow the hand to be laid between it and the withers.

Careful fitting of the collar may come to nothing if the hames do not fit properly. The top hame strap, if rightly adjusted, will neither pinch the top of the neck nor be so loose as to allow rubbing. The lower hamestrap should be buckled tightly to insure a snug fit of the hames against the collar. If the tugs are properly adjusted the line of draft will be at right angles to the collar bed and the pull will be evenly distributed over the shoulder. This usually means that the tugs should be fastened at a point one-third of the distance from the point to the top of the shoulder. The traces should always be the same length; if not, there is a side pull on the shoulder.

Then if care is used in hardening the horse to the work, little trouble will result. Frequent stops are of advantage to the shoulder and an occasional lifting of the collar helps. Bathing the shoulder at night with cold water restores circulation and hardens the skin. By cleaning the collar each morning, a smooth surface is brought in contact with the shoulder, and rubbing which might result in a breaking of the skin is avoided.

With the best of care, however, sore shoulders cannot always be avoided. As long as the swelling is well defined and movable, the skin alone has been damaged. This is best treated by carefully washing the surface. Some good shoulder washes are: (1) Alcohol, 1 pint, and the white of two eggs, thoroughly mixed. (2) A solution of silver nitrate, 10 grains to 1 ounce of water. (3) Carbolic acid, one pint in 15 parts of glycerine.

After the surface has been thoroughly cleansed, the wound should be powdered with iodoform mixed in flour or starch. In the case of a wound affecting the deep-lying tissues, the treatment is more involved and the injury much slower in healing. The wound must be kept thoroughly cleaned with an antiseptic and the horn-like substance removed. If the wound must be lanced, the skin should not be divided transversely, but need not be spared longitudinally. The injured spot should be protected by means of a hole cut in a pad, if the horse must be worked.

B. C. ZIMMERMAN.

FITTING HORSE COLLARS

A collar should be fitted to the horse, and not the horse to the collar. The collar that is too large should not be used on a horse in the hope that he will grow large enough so it will eventually fit. A collar that fits well in the spring may not fit at all in the fall.

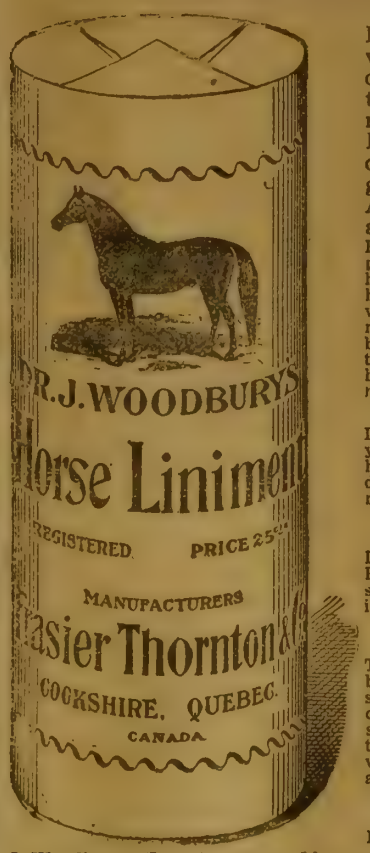
When one is fitting a horse with a collar, the animal should be standing in a natural position on level ground, with his head held at the height maintained while at work. The collar, when buckled, should fit snugly to the side of the neck, and its face should follow closely and be in even contact with the surface of the shoulders from the top of the withers to the region of his throat. At the throat there should be enough room for a man's hand to be inserted inside the collar.

The style of horse collars are created mostly by the use of different kinds of materials in their construction. Such materials as heavy duck, ticking, and leather are used either alone or in various combinations. All-metal collars may also be bought, but are not so much used.

The stuffing used in horse collars is coarse material, such as rye straw, curled hair, and cotton fiber.

Dr. J. Woodbury's Horse Liniment

THE INFALLIBLE REMEDY



For the removal of Splints, Bog Spavins, enlargements of any and every description it has no equal. Given internally, it will promptly relieve and remove any and every character of Cough Enlargements of the Glands, Affections of the Kidneys. For distemper, strangles, and colic it is infallibly the remedy All horses that are stabled should have an application of Dr. J. Woodbury's Horse Liniment to the hoofs of the forefeet to prevent their becoming feverish, dry, brittle, hard, contracted or otherwise injured. Insist on having Dr. J. Woodbury's Horse Liniment. We warrant it to effect that for which it is recommended when used according to directions. Its beneficial effects are so prompt and decided that it has excited the admiration of the leading horsemen of the Dominion and secured their highest confidence.

Bear River, N. S.

Dear Sirs:—We do not hesitate in recommending your Dr. Woodbury's Horse Liniment. We have used it in the woods for coughs, colds, distemper and cuts and would say that no lumberman should be without it.

Yours truly, Clarke Bros.

Hubbard's Cove, N. S.

Dear Sirs:—I have used Dr. J. Woodbury's Horse Liniment in my stable for years and consider it the best liniment on the market for both internal and external use.

Yours truly, C. C. McLean.

Truro, N. S.

This is to certify that I have used Dr. J. Woodbury's Horse Liniment with the very best results for colds, coughs, distemper and all lung deseases. It is the best to give horses in the spring to keep them in condition. It purifies the blood, cleanses the lungs from impurities which may exist and gives the system healthy action.

Newton Lee, Owner "All Right" 5817.

Elmsdale, N. S.

Dear Sirs:—Kindly send me 6 dozen bottles Dr. J. Woodbury s Horse Liniment. I have not a bottle in the store and it is the only kind my customers will take. Yours truly, Elmsdale Mercantile Co.

Elmsdale, N. S. Dear Sirs:—I cured my horse with Dr. J. Woodbury's Horse Liniment. It was a bad case of distemper. I always recommend this liniment to my friends as the best for all diseases of the horse. Yours truly, H. R. Whitehead.

Dear Sirs:—One of my horses had a bad cough and I made a complete cure with three bottles of Dr. J. Woodbury's Horse Liniment. The cough was of twelve months standing. In my large experience with horses I consider this liniment to be the best made for all diseases in the horse, I recommend it to my friends. E. J. Anderson, Truro, N. S.

This New Farm Boot

CHROMOIL TANNED
BY
Palmer-McLellan
FOR SUMMER WEAR
POSTPAID TO YOU FOR
$4.50

The wonderful chromoil leather in these boots is a big improvement on the best ordinary "Oil-Tan." It is waterproof not only on the surface but all the way through. It does not dry out nor crack from heat, nor stiffen up quickly from frost. It retains through everything the soft suppleness that makes it so comfortable.

The shape, too, is new and better, combining the easy comfort of the Indian moccasin with the permanent form of a regular boot. This is ensured by building it on a last, and giving it a solid extra long counter in the heel. It's a boot that will stand up to the hardest kind of service, in any weather, and outwear any other working boot you have ever tried.

At the same time, it is light in weight and easy on the feet, and remarkable value for the price.

If your dealer cannot supply you with these new Palmer-McLellan Chromoil Tanned Farm Boots, mail us the price and we will ship you a pair postpaid.

Men's	Sizes	6	inches high,	per pair	$4.50

HOW TO MANAGE STALLIONS BETWEEN BREEDING SEASONS TO INSURE THEIR VITALITY

Many stallion owners treat their animals somewhat in the same manner that careless farmers treat their implements, by throwing them aside to rust and waste through lack of exercise or care in regard to future usefulness. The fertility of a stallion depends greatly upon the condition in which he is kept during his off season. It is not at all necessary for a stallion to be fed up to the ton standard, to ensure his vitality as a stock-getter—in fact it is likely to damage him if he is fed to that extent without due regard to exercise. The stallion owner who feeds the horse to secure the admiration and popularity of farmers who own breeding mares is treading on very thin ice in regard to his business. No up-to-date judge or breeder will place any trust in the horse that has only abnormal fat to advertise his qualities. Nor, on the other hand, will the neglected horse that is not overburdener with fat be any better a stock-getter, simply because he has not got the fat, if his off season time has been spent in idleness, isolation and neglect. Just in the same way as the skilled dairy farmer secures success, by reference to his cow's records, so will the successful horse breeder succeed. The main point of the mare owner is to find out the fertility record of the horse and the stallion owner should be prepared to furnish records of his horse that will prove his fertility.

Evils of Small Box Stall

To gain this end must be the chief aim of the stallion owner. Close confinement of animals interferes with their fertility, and confining the stallion to the small dark box stall for 8 or 9 months of the year, is a practice that is proving to be one of the greatest wasters in the horse industry. Stallions that are fed upon a generous ration of highly nutritious food and are not given regular exercise, become more or less sterile. Practical breeders recognize this and seek means to prevent it. Breeding males that have proven themselves of great merit are those that have led the active life, and have been handled by men who fully recognize that natural conditions must, in as far as possible, be given to the domesticated surroundings. The owners of draft stallions in Scotland, who are not catering to the call of exhibitions, work their stallions throughout the year, and these stallions are notoriously sure foal-getters. They not infrequently have records of 95 per cent. of the mares in foal. The modern plan, adopted by the fancy breeder, of keeping the draft stallion in high condition and standing him for service at one barn, thus requiring all mares to come to him, is undoubtedly reducing the fertility of draft stallions.

Keep Stallion in Natural Condition

It is considered a loss to the stallion, as well as to his owner, to keep him in idleness, and most owners train the draft stallion to harness and employ him at work. It will pay any stallion owner to plan some work for the stallion, and in Scotland, if no facility is available on the farm to work the horse, he is let out for carting work, but is always attended to and worked by a capable attendant, hired by the owner. So long as the general conformation is not spoiled by undue strain, a lack of flesh in the fall and early winter when at work is found beneficial.

A study of the conditions found in nature will illustrate the utility of this method. An animal that is maintained in a uniform condition of excessive fatness is not in the best condition for the successful exercise of the breeding function. A rapidly improving condition through regular and judicious work or exercise is in line with the natural condition. In nature it is rare for an animal to remain continuously in a fat condition. The rigors of winter and the exercise necessary in searching for and procuring sufficient food is the ideal condition illustrative of the method for the owner of the domesticated animal to apply. Then, in the spring time, when the rapidly improving condition of the animal in nature is proceeding through a more abundant supply of nutritious food, the animal is in the fittest form for breeding and the natural desire is accelerated. This is the essential condition in which the domesticated animal can also best perform the work of reproduction. It must be remembered that the taking away of nutritious rations alone during the off season is not enough to generate the desired fertility. It must be accompanied by sufficient exercise, comparative with the animal in nature in its search for food when snows lie deep and vegetation almost nil.

Daily exercise must take the place of the lonely box stall, and this can in no way be better done than by judiciously employing the horse at work. Experience has clearly demonstrated that the well bred stallion makes a superior servant at work. He is more intelligent and more willing than any other class of draft animals and, above all other animals bout the frm, is the most easily domesticated.

No farmer or stallion owner can afford to keep a stallion in fit condition with proper exercise and attendance without employing his services in some useful field of labor, and no better method can be adopted that so nearly fulfils the law of nature that finds all animals in perfect condition for breeding. It must be remembered that in getting down to the thin condition through sheer neglect, confined to a small bax stall during winter, is entirely opposite to nature and only makes doubly sure that infertility will follow. The reduction of the high condition must come by regular work or exercise, not by the isolation and neglect that are the surest highroads to the decay of all organisms that make for vitality in live stock.

Nuts and bolts rattle off of new machinery like ripe grain out of the sheaf. Put nuts on with a little paint or red lead. Take a cold chisel and fix all nuts for keeps if they are not to be taken off for adjustment of parts.

Lend Your Profits to Your Country

PRESENT prices for agricultural products ensure good profits to the farmer.

To pay war expenses the Government needs these profits, and will pay you over 5% interest on them. Sir Thomas White, Minister of Finance, says: "A War Savings Certificate in every Canadian home will help to win the war."

For every $21.50 you loan to Canada now, you will receive $25 at the end of three years. War Savings Certificates are issued in denominations of $25, $50 and $100, selling at $21.50, $43 and $86, respectively, and may be purchased at any Bank or Money Order Post Office.

PRESERVE EGGS NOW

The indications are that eggs will be dear next winter, dearer than they were last winter, so those wro want eggs had better put some down now while they are comparatively cheap. Do not use oats, bran, salt or such mediums; moreover, the patent preservatives usually advertised as being so simple and effective had better be adopted with caution. Better use something that has been tried and found satisfactory.

According to Dr. Frank T. Shutt, Dominion Chemist, lime water is one o fthe best preservatives and we quote the following from his Exhibition Circular No. 42.

The method of preparation is simply to slake one pound good quick lime with a small quantity of water and then stir the milk of lime so formed into 5 gallons of water. After the mixture has been well stirred for a few hours it is allowed to settle. The supernatant liquid, which is now "saturated" limewater, is drawn off and poured over the eggs, previously placed in a crock or water-tight barrel.

As exposure to the air tends to precipitate the lime (as carbonate), and thus to weaken the solution, the vessel containing the eggs should be kept covered. The air may be excluded by a covering of sweet oil, or by sacking upon which a paste of lime is spread. If, after a time there is any noticeable precipitation of the lime, the lime-water should be drawn or siphoned off and replaced with a further quantity newly prepared.

General Precautions Necessary to Take

It is essential that attention be paid to the following points:—

1. That perfectly fresh eggs only be used.
2. That the eggs should throughout the whole period of preservation be completely immersed.

Although not necessary to the preservation of the eggs in a sound condition a temperature of 40° F. to 45° F. will not doubt materially assist towards retaining good flavour or rather in arresting that "stale" flavour so often characteristic of packed eggs.

Respecting the addition of salt, it must be stated that our experiments—conducted now throughout fifteen seasons—do not show any benefit to be derived therefrom; indeed, salt frequently imparts a limey flavour to the egg, probably by inducing an interchange of the fluids within and without the egg. Our advice is, do not add any salt to the limewater.

POULTRY FACTS WORTH READING

Hatching for pullets for winter laying is over. Rearing will be the main interest from now on. It will be good practice to bring off an occasional hatch through the summer and fall to supply friers for the home table, but no one should think of saving the pullets and carrying them over winter. They will never pay for their keep.

Have the hatchings been satisfactory? If so, beware of carelessness. There is still a fine chance for failure. If the May hatchings have to be drawn on to make up the required number of pullets for winter laying, it will be well to remember that such stock is handicapped by lateness and that extra care will be needed to enable them to overcome that handicap.

Free Range Not Enough

No matter how ample and rich the range may be, all pullets for winter laying, the late hatched in particular, will need extra feeding. They should have at least two feedings of grain daily and they should have access to a dry mash that carries some meat or fish scrap. The unprecedented high price of all grain feeds and grain by-products is forcing all of us to do some close figuring. We simply must practice every possible economy in order to make poultry keeping profitable, but as the requirements of growing pullets do not take world wars into consideration we should prod ourselves frequently lest we practice economy to the detriment of the growing stock and so defeat in the end the very object of all our poultry work-profit. Pullets for winter laying must be mature in body and organs by cold weather, and any economy or neglect that postpones maturity will make the keeping of such stock unprofitable.

High Prices Next Winter

The prevailing opinion is that eggs will command high prices next fall and winter. Some are predicting a price of one dollar per dozen next Christmas, and this may come to pass. Whatever may turn out to be the upper limit, the average price will be considerably higher than the average of last season.

The high prices for eggs in PROSPECT is the justification for extra care and the feeding of extra high-priced feeds. If the product commands the right price, the producer should not worry over an apparent and imaginary high cost of production. If eggs brought ten dollars a dozen, poultry keepers could afford to pay one-half a cent a GRAIN for corn.

Keep No Drones

Poultry keepers should learn wisdom of the bees—they do not winter drones. The precious honey and pollen must be reserved for the spring workers. The egg-laying contests have proved that the best flocks have unprofitable individuals, what dairymen would call boarders. City and village poultry keepers have noted this fact. Having to buy all feeds, they are compelled to make their layers pay their way, and if any individuals do not pay for their keep such unprofitable fowls are prepared for the home table or for market. Fruit growers and farmers have been very slow to learn the lessons illustated by these laying contests. The fowls received such feeds as were produced on the place, and the women used and sold such eggs as those fowls chose to lay. These two operations defined farm poultry keeping. But farm people generally are beginning to keep watch over all the feeding operations on the place. They had learned to figure the value of feeds in the terms of horse-power, of butter and milk, of bacon. At last they have come to figure the value of the feed given to the ppultry on the place. Maybe the value of grains fed to the chickens is estimated, but the point is, fruit, growers and farmers are coming to understand why closer attention should be given to the production of all individual animals and fowls kept on the place. The loafers, the boarders, the drones, must go. The high cost of feeds is their doom.

A Money-Making Pullet

The Kentucky Experiment Station reports that one pullet in the egg-laying contest held at that station has laid 95 eggs in 95 consecutive days. This is beileved to be the world record; certainly the official record. Of course this is a remarkable pullet—one in a million. But you may have just such a pullet in your own flock. Have you any way of finding out? Perhaps not. But there is a way—the use of the trap nest, a nest with some kind of trigger or trap that confines the fowl until removed by an attendant. The leg band being numbered, the attendant can make the proper record on the card prepared for the purpose. In this way non-producers are detected and removed from the laying house. In addition to the prompt reduction of unprofitable

PEDLAR'S "GEORGE" SHINGLES

Everywhere facts
prove the menace of lightning.

Once you realize that the danger of lightning lies in its concentrated action on a single spot in your roof, you will appreciate the safety and protection of a Pedlarized roof. Pedlar's "George" Shingles lock together on all four sides, forming a single sheet of metal from eave to ridge. Lightning cannot concentrate on any single spot, for Pedlar Shingles spread it over the whole surface of your roof. When properly grounded, a Pedlarized roof is practically indestructible. This summer know the saving and peace of mind of a safe, steel roof by Pedlarizing now with "George" Shingles. Write for the "Right Roof" Booklet M F

The Lock that Holds

A Schoolmaster Recommends
MILBURN'S LAXA-LIVER PILLS.

Men and women in all walks of life who occupy sedentary positions are more liable to liver troubles than those who are active from morning till night.

When you don't get the proper exercise the bowels do not move regularly, your liver becomes sluggish, the breath becomes foul, specks float before the eyes, everything turns black, constipation sets in and brings in its train numerous troubles that could be prevented if the bowels were only looked after properly.

Milburn's Laxa-Liver Pills will and do regulate the bowels, and keep you in a state of excellent health.

Mr. J. G. Hamilton, Schoolmaster, Cornwall, Ont., writes: "I have great pleasure in recommending Milburn's Laxa-Liver Pills. I am a teacher, and all the time I do not get the requisite amount of exercise I need, so I was troubled with sour stomach, yellow eyes, and specks floating before my eyes. I purchased 5 vials of your pills, and have just finished them.

Now I am feeling all right."

Milburn's Laxa-Liver Pills are 25 cents a vial at all dealers, or mailed direct on receipt of price by The T. Milburn Co., Limited, Toronto, Ont.

DYSPEPSIA MADE A WRECK OF HER

Ontario Soldier's Wife made worse by ordinary remedies, but soon cured by Dr. Cassell's Tablets.

Mrs. Mary Lawrence, 9, May-place, Kitcheree, Ont., writes:—"Dr. Cassell's Tablets have made me a new woman. I used to be terribly depressed and suffered so much from Dyspepsia that I was almost a physical wreck. I tried various things, which only seemed to make me worse, and then at last I got Dr. Cassell's Tablets. They changed my whole outlook on life. I am well now, I romp with my children, and am looking hopefully forward to my soldier husband's return."

A free sample of Dr. Cassell's Tablets will be sent to you on receipt of 5 cents for mailing and packing. Address: Harold F. Ritchie and Co., Ltd., 10, M'Caul-st. ,Toronto.

Dr. Cassell's Tablets are the supreme remedy for Dyspepsia, Kidney Troubles, Sleeplessness, Anaemia, Nervour Ailments, and Nerve Paralysis, and for Weakness in Children: Specially valuable for nursing mothers and during the critical periods of life. Price 50 cents per tube, six tubes for the price of five, from Druggists and Storekeepers throughout Canada. Don't waste your money on imitations; get the genuine Dr. Cassell's Tablets.

Proprietors, Dr. Cassell's Co., Ltd., Manchester, Eng.

THOMAS J. HOGAN.
The Champion Clog and Pedestal Dancer of Canada.

expense, the trap nest becomes the basis of intelligent breeding. It finds the profitable laying pullets, and the profitable laying pullets become the profitable breeding hens the following year.

It is only fair to say that the use of the trap nests involves frequent visits to the hen house, and hence there is some question as to their general use on the farm. The ideal, however, is there, and the way to it is now open. Every poultry keeper must figure out his own problems. One thing is certain, the poultry keeper who studies the report of any one of the national egg-laying contests will never be the same. He may not introduce trap nests, but he will manage in some way to improve his flock and increase the profits. And this is one of the results of finding out that there is a better way of doing things.

CULL THE FLOCK OF POULTRY NOW TO MAKE PROFIT

The urgent need of conservation demands that all poultry not paying its way in either eggs or growth be killed for eating.

The present high prices of feed also make the keeping of such classes of poultry decidedly unprofitable as well as unpatriotic. Therefore, for your own good and for the good of the country, kill them.

There are in every poultry yard birds that have outlived their usefulness and others that will never pay their way; these might profitably be finished and marketed, not necessarily all at once, but as soon as practicable, taking into account the market, etc.

In these classes might be mentioned, in the order in which they should be disposed of, the following:

1. MALE BIRDS. The breeding season being over, all males should be fleshed and killed. It will cost $2.00 or over to keep each male until next breeding season, therefore, get rid of them; it will also be better for the layers, the eggs and the growing chicks.

2. TURKEYS AND WATERFOWL. Toms and turkey hens, geese and ducks not absolutely needed for next year's breeding should be disposed of.

3. HENS. All hens of the heavier classes that are two eyars old and over might better be marketed now. In even the light classes many of this age ought to go. Others that are laying but that are not worth keeping for another year should be kept until the egg yield does not pay for the feed. Better still keep culling out those that show signs of early moulting as you go along.

The best of the one and two-year-olds of the lightest breeds might pay to keep all summer, but only the year-olds should be kept over winter, and even these will stand culling fairly closely.

4. BROILERS. If broilers are early it pays best to sell the cockerels when two or three pounds in weight rather than to keep till heavier. This is especially so when the sexes cannot be separated and where the runs are small the pullets will soon require all the room and green feed available.

Light breed cockerels should be sold early; it selodm pays to feed them to maturity.

5. ROASTERS. Don't leave the marketing of all roasters till late in the fall.

KEEP THE PLOUGH GOING AND RESTORE THE WASTED LAND

Keep the plowing going this fall whenever possible. It will be useful in many ways. A light plowing, where the land is not seeded, is a fine thing to check the growth of many weeds and to keep others from going to seed. Later in the fall it should be plowed for spring cropping.

DELCO-LIGHT
ELECTRICITY FOR EVERY FARM
Lights the Farm and Lightens Farm Work

Delco-Light will give you all the light you need for your home and outbuildings. It is cool, clear, safe. No smelly, dirty lamps or lanterns. Less housework. No fire danger. Better light for chores—no lantern to hold.

Delco-Light provides power for all your smaller machines. Gives you running water. Does the washing and ironing. Saves time and money indoors and out.

Delco-Light is a simple, economical, easily operated plant. Comes complete, ready to use. A child can operate it Full information and free literature by writing your nearest distributor. Price, No. 208—$485 and No. 216—$585.

All land intended for spring cereals or root crops should be plowed in the autumn. In the spring the rush is on and nothing that can speed the work of seeding should be left over until then. In almost every case the early sown grain leads in yield and quality of crop.

In order to grow good crops an immense quantity of moisture is required. The normal rainfall is not nearly equal to the requirements of any soil. Fall plowing conserves moisture and greatly assists in securing the needed supply. The surface of the land, being made rough by the action of the plow, is capable of holding larger quantities of rainfall and snow, and as the soil immediately below the surface, being broken up into fine particles, is able to absorb larger quantities of this water than land which is smooth and hard, a much greater supply is therefore stored up for the use of plants. If this land is then cultivated and sown with grain at the first opportunity in the spring, which may usually be done where the land is fall plowed, the greatest conservation possible is made of this moisture; as well as of all moisture below it and which is being constantly brought to the surface by the capillary action going on in the soil.

Not only from the standpoint of production of crops in autumn plowing the proper thing to do, but also from that of economy of labor. At this time of the year the land is usually in ideal condition for plowing. The cool weather is right for the teams to accomplish a heavy day's work and the rains which usually occur put the land into excellent condition for this work, consequently a much greater area can be plowed in the same time than in the spring, when the teams are soft, the ground hard and the weather hot, which is likely to be the case unless the plowing is done very early—before the spring seeding is commenced.

There are acres more in sod than was the case four years ago, with no corresponding increase in live stock. Much of this is old meadow or pasture with little feed on it, and by some means should be brought into profitable production. Hay is cheap and not required in larger quantities. The great need is for cereals. In this matter, however, as in all other farm practices, one should use good judg[illegible] properly managed. There is nothing to be gained, but much to be lost, in multiplying acres and not increasing the production.

"ACME" STARCH

For all fine starching, use "Acme"—white or blue —it does perfect work. In 1 and 2½ lb. packages.

FOR HOME AND COUNTRY

This Department will be utilized to the best interests of the homes in the Maritime Provinces. Subjects relating to household science and all that stands for better homes and communities will be published on this page. The editors, Misses Saunders and Winter, of Fredericton, N. B., solicite your assistance in making this page a success and will be glad to publish tested recipes, household discoveries and other articles useful to the homemaker and women's organizations.

THE MONTH OF RIPENESS

By William Campbell

Thou languid August noon,
When all the slopes are sunny;
When with jocund, dreamy tune,
The bees are in the honey
When with purple flowers,
A-baming in the sun,
The drowsy hours
Thread, one by one,
The golden pleasaunces.

Then is heart's musing time,
Then, of all the seasons,
Old Earth for inward rhyme,
Is full of golden reasons;——
Then the ripening gourd,
The sun-kissed garden wall,
The purpling hoard,
The flocks that call
Adown the distances.

Forgo the saddening tear,
Thou Month without alloy;
To younger seasons of the year
Resign the flag of joy;
But thou, be what thou art,
Full brooding to the brim
Of dreams apart
And purlieus dim
Of leafy silences.

THE PRESERVATION OF FOOD

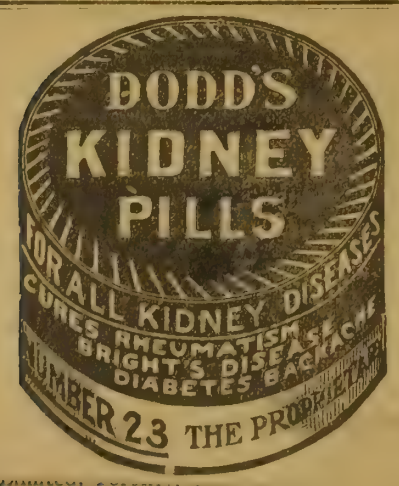
The following has been taken from a recent bulletin (252) issued by the Ontario Department of Agriculture, Toronto, and compiled by Miss Ethel Chapman. Send for it. It is excellent.

Home Canning: Drying Fruits.

The necessity of saving every pound of produce grown this year, will, no doubt, revive the practice of drying fruits on many farms. While it is difficult to give any fast rules to follow with the equipment used in the average home, where the fruit is dried mostly on racks over the stove or in the oven with a slow fire, the following methods used in kiln evaporators give some idea of the temperature and time required for drying.

In the kiln evaporator, most operators maintain a temperature of 155 to 165 degrees for the first five or six hours. If the temperature is raised higher than this the cellular structure of the fruit is destroyed, and a great deal of sugar lost by bleeding. Unless the temperature is kept up to this level, the surfaces of the fruit become slimy and further drying is retarded. By these signs, the housekeeper can regulate the temperature even where her equipment does not permit the use of a thermometer. After the first five or six hours some operators allow the tempeature to go down to 130 or 135 degrees, open the ventilators widely, and continue the drying by using large volumes of air at lower temperature for ten to twelve hours, after which the temperature is bought up to 175-180 degrees, and kept there until the drying is completed. Those who use this method claim that it is economical of fuel, and that is makes a more springy, "lively" product.

In drying prunes, and berries, cherries, currants, etc., the temperature at the outset should not be allowed to rise above 125 or 130 degrees until the fruits have lost a considerable part of their water, as otherwise there will be expansion and bursting with consequent dripping. If ample air can be obtained, or if a good draught can be had through the kitchen where the fruit is being dried, a higher temperature, from 185 to 180 degrees may be employed in the last half of the drying period. If there is not a free circulation of air, however, the temperature must be kept below this point or the fruit will be partially cooked or dried outside while the inside is still moist.



To Determine When Apples Are Sufficiently Dried

Apples should be removed from the drying trays while they still contain slightly more moisture than the finished product is to have. One can learn only by experience how to judge accurately when the fruit is ready to remove, but some general tests may be used. If the fruit is sufficiently dry to take from the dryer, it will be impossible to press water out of the freshly-cut ends of the pieces, but they will be sufficiently elastic not to break when the piece is rolled into a cylinder. When a mass of slices are pressed firmly into a ball in the hand, they should separate at once when released. When the fruit has reached this condition it should be spread out on the floor or on a table in a dry room, to a depth of a foot or more, and stirred thoroughly once a day.

Iome idea as to whether apples have been sufficiently dried may be gained by weighing them before and after drying. An average yield of dry fruit from Baldwin, Spitzenburg, or Ben Davis will be 13 to 13½ pounds from 100 pounds of fresh fruit. Jonathan and Greenings will yield from 13½ to 14 pounds per hundred of fresh fruit, while varieties like Russet and Grimes Golden will give from 14½ to 16 pounds. Windfalls and immature fruits will make a slightly lighter product as they must have the water content reduced to a lower percentage in order to prevent spoiling.

Sun-Dried Fruits

Rules which apply to such fruits as cherries, plums, peaches, quinces, apples, pears, apricots, are as follows:—

All fruits must be perfect and ripe. Cherries should be stoned before drying. Plums are wiped clean and stoned. Firm, ripe peaches are better if dried with the skins on. They must be brushed with a small vegetable brush or wiped with coarse towels, cut into halves and the stones removed. Apricots are prepared the same as peaches, but apples, pears and quinces are pared and cut into quarters and eighths, depending on the size of the fruit.

All fruits are dried in the same way: Spread them in a single layer on a board; have small posts at each corner of the board; cover it with a piece of mosquito netting, and set the board in hte hot sun. When the sun is down bring the fruit indoors. Next morning turn the fruit over, and set again in the hot sun. If there should be rain or damp weather, the drying will have to be finished in a very moderate oven. If dried in the oven, care must be taken not to scorch the fruit.

The fruit must be perfectly dry before putting it into flour bags or sugar bags. When filled, tie the bags and hang them in a cold, dry place.

For sun-drying, about three hot, sunny days will be required, and the fruit must be turned quite often.

BEWARE OF FLIES

Flies should be kept out of our houses, killed if they enter them, and prevented from hatching their eggs in stables, manure heaps, swill pails, and other filthy places. They are born in filth; they feed on filth; they walk on filth; and then, with filth sticking to their feet, legs, and bodies, they feed and walk on the food which has been prepared for human beings to eat. It would disgust us, wouldn't it, if we saw a fly feeding on the filth of the street, the stable, the garbage can, or on something even worse, and then saw the same fly go through the open door or window of our dinging-room and wipe its feet n the sugar, tangle its legs in the butter, or take a bath in the milk? If we should watch every fly that comes into the house, we would see that most of them had come from such filth to the food on our table.

Flies are Dangerous

Bad as filth is, it is not the worst thing that flies carry about. They swarm about open sewers, drains, and outhouses which receive millions of disease germs which have passed through the bodies of sick people. Flies in this way pick up and carry on their bodies, heads and legs (which are covered with fine hairs—just suited for catching and holding this sort of thing) the germs of typhoid fever, summer diarrhoea of children, tuberculosis, and several other diseases Dr. L. O. Howard, Chief Entomologist of the United States Department of Agriculture, calls the common house fly the Typhoid Fly, because so many cases of typhoid fever have been caused by its carrying the germs from one sick person to another. These germs are so small that you cannot see them without a microscope, but the fly that is eating from the same plate with you may be carrying a million of them.

Flies kill more people than wild beasts and poisonous snakes. Many of these beasts and snakes never get a chance to kill any human being; but any one of the millions of flies found in most of our towns and cities has a chance, if it comes into a house carrying typhoid germs, of killing a whole family.

Flies Breed Quickly

Most house flies in cities are hatched from eggs which have been laid in horse manure. Some breed in other forms of filth, such as garbage cans, heaps of refuse in back yards, etc. The fly lays 120 or more eggs at a time. These, if they are not distributed, become maggots in about 12 house. In from five to eight days more, the maggots enter the pupa state, as caterpillars do, and after from five to seven days out of the earth or manure in which they have buried themselves in the form of flies, ready in a few days to become the fathers and mothers of large families. They breed so rapidly that in one summer the children and grandchildren of one pair of flies may amount to thousands of millions. And remember that the germs they carry multiply much faster than the flies.

To prevent flies from breeding, screen the stables if possible. Remove the manure at least twice a week. If flies begin to breed in stored manure they may be killed by thoroughly spraying it with kerosene or Paris Green, and then pouring on enough water to wash the oil or poison well in. The objection to the use of kerosene is that it ruins the manure for fertilizing purposes.

It is well to abolish old-fashioned outhouses where possible. Where this cannot be done a liberal amount of lime should be used, applied in small amounts daily. Chloride of lime is better than slaked lime, but slaked lime is better than none at all. Garbage barrels should be thoroughly cleaned after emptying, and the contents should be sprinkled with crude oil, lime, or kerosene oil. And finally keep flies out of the house by screening the doors and windows.

Your Range Should Have

—a dependable oven, a good warming closet, a durable and ample-sized firebox, easy-working grates, simple draft control and a finish that requires but little attention to keep clean. All these and many other desirable features will be found in

Everjet Elastic Paint

An Ideal Farm Paint

Around the farm or home, wherever you have surfaces exposed to wind, wear and weather, you can save money and the trouble of renewing things, by using Everjet Elastic Paint.

Carbon paints are the most durable of all and Everjet is the best carbon paint ever made. It is the ideal roof paint. Stops deterioration and leaks; adds a good many years to the life of a roof.

Wonderful on metal surfaces because it is elastic and will not peel or crack under temperature changes. It will keep your implements fit. Try some. You will never be without it.

Barbers Itch Eczema

BARBERS' itch is in reality a form of eczema. The delicate skin becomes irritated from shaving, a little infection gets in, and soon burning, stinging eczema is set up.

Fortunately, there is cure for Barbers' Itch and Eczema in the use of Dr. Chase's Ointment, and once you have made the acquaintance of this soothing, healing ointment, you will always keep it on hand to apply after shaving. Not every time, but whenever there is roughness or irritation of the skin.

Mr. Chas. A. Duxbury, Meaford, Ont., states:—"While out in the Northwest I caught barbers' itch, and anyone who has had it will admit that it is not at all pleasant. It began on my neck below the chin, and spread until I became alarmed. It itched so bad that I had to scratch it, and that only made it worse.

"A friend of mine told me to use Dr. Chase's Ointment, and I did so. The application of this ointment gave prompt relief to the itching, and it was not many weeks until I was entirely freed of this annoying ailment."

Some of the ingredients of Dr. Chase's Ointment are very expensive, and for this reason imitations and substitutes are offered because they afford greater profits to the dealer. They will only disappoint you. The genuine Dr. A. W. Chase's Ointment will positively cure.

CLOTHES FOR THE GROWING CHILD

Very much of the comfort of a child depends upon his having the right kind of clothing. This is especially true in summer. One hot day a mother came into an infant-welfare station in a large city, bringing a screaming baby who would not be pacified. The trained and sympathetic eye of the nurse in charge saw that the little feet were covered with knitted woolen socks. She asked the mother to take them off. Immediately the screams ceased and the baby stretched his naked feet in delight at being relieved of the intolerable irritation.

During the hot months children should wear just as little clothing as possible. Babies require only a diaper and one other garment, while runabout babies and children up to five will be amply clothed in waist and drawers, with one other garment, preferably a cotton slip, apron, or rompers, or one of the many similar garments illustrated in the pattern books.

The one-piece dress is a great boon to busy mothers, being easy to make and to wash and iron. If the kimona sleeve is used, the dress will be cooler, but in some garments the set-in sleeve is less clumsy and wears better. Rompers, loose at the knee and low-necked and short-sleeved, may be used for little girls and boys alike. Denim overalls are rather cumbersome for the hottest weather, but are adapted to cool days.

Starched, frilled, and fussy garments are all alike unsuitable for young children, whose clothing should be such as will make them perfectly comfortable and permit the freest play. No child should have to think of his garments during the play hours; he should of course be subject to reasonable restrictions upon wilful or mischievous soiling or destruction of his clothing.

Cotton is the best material for outside garments, since a child of this age should have no clothes that can not be washed. Mothers disagree as to the comparative merits of white clothing and colored. White garments may be boiled, and thus the amount of rubbing necessary to get them clean is very greatly lessened. On the other hand, white dresses are soiled almost as soon as the child begins to play out of doors. It must be remembered that while white or light colors show the soil sooner, there may be just as much actual dirt on the darker ones. It must also be remembered that light colors like blue, green, lavendar, or pink are almost certain to fade unless they are washed with special care. Striped and check ginghams fade less than plain materials, but often shrink badly in washing. Such materials should be shrunk before being made up. Seersucker and cotton crepe materials of many kinds have the great advantage of needing no ironing. These rough materials are not very cool, and if used for summer wear should have short sleeves and round neck to avoid chafing of the skin of the arms and neck. Percale, galatea, madras, and the better grades of gingham or dress linen are all good materials for children's clothes. For hot weather almost any of the thin materials may be used.

Corn-Meal-and-Wheat Bread

1½ cups milk, water, or a mixture of the two; ½ cake compressed yeast, or 1¼ cups milk, water or a mixture of the two; ¼ cup liquid yeast; 1½ teaspoons salt; 1 tablespoon sugar; Butter (if used), 1 tablespoon; 1 cup corn meal; 2 cups wheat flour.

Method: Pour 1¼ cupfuls of the water over the corn meal, salt, sugar, and fat (if used), and heat the mixture gradually to the boiling point or nearly to it and cook 20 minutes. This cooking can best be done in a double boiler. The water is sufficient only to soften the meal a little. Allow the meal to cool to about the temperature of the room and add the yeast, mixed with the rest of the water (¼ cupful), or the ¼ cupful of liquid yeast. Mold thoroughly, let rise until it doubles its bulk, make into a loaf, place in a pan of standard size, allow to rise until it nearly fills the pan, and bake 45 to 50 minutes.

THE RELATION OF MENTAL AND PHYSICAL WORK

One of the effects of physical work is the lowering of mental functions. One of the results of mental exertion is physical exhausiton. There are not, as has formerly been supposed, two kinds of energy, mental and physical. The body produces one kind of energy only. If we use up that energy doing physical labor, we unfit ourselves to do mental labor. If we sit down to read or study after a day of hard physical exertion, we find ourselves drowsy and our mind slow and dull. This is the reason the man who works hard physically has little or no ambition to study at the end of the day. If we undertake physical labor when we are mentally exhausted, we tire quickly.

If we have mental work to do, we should not take it up when we are exhausted from physical work or violent exercise. Our mind is at its best after a good sleep or when the body is rested and fresh. Violent exercise does not freshen the tired mind and is not the proper recreation for the mental worker. Exercise, no matter of what kind, uses up energy. Light exercise is beneficial after exhausting mental labor because it permits the parts most exhausted to rest while the parts least exhausted are being used and it stimulates respiration and the pulse, so that the process of upbuilding goes on more rapidly.—Alfred Westfall, Colorado Agricultural College.

CHEMICALS IN HOME SHOULD BE SAFEGUARDED

One cannot use too much care or caution in handling and storing poisons and chemicals in the home. The writer's attention has just been called to a recent case in which a lady caught up a bottle of what she supposed was a face lotion, poured some into her hand and rubbed it on her face. It was not face lotion, but carbolic acid. Luckily, none of the acid got in her eyes, but her face and hands were badly burned. The writer has known of several similar cases.

THE SUSSEX MANUFACTURING CO., LTD.

SUSSEX, - - New Brunswick

as when a barber applied carbolic acid instead of bay rum to a customer's face; and when another person took a mouthful of ammonia water instead of tooth wash. All of these accidents, and most of those of like character, resulted from haste, and from carelessness in storing, labeling or handling dangerous substances.

Many plans have been suggested for avoiding mistakes of this kind, such as having containers of special form —three-cornered, corrugated, and screw-top bottles; pins thrust through cork; tiny sleighbells tied to the bottle; and many similar devices. Every person in a household should either fully understand what chemicals are kept in the house, where they are kept, and how they should be used, or should not be able to get at such chemicals at all.

Have every bottle of medicine, and every dangerous chemical, no matter how often or much it is used, in a distinctive substantial container with a proper and permanent label. Make it impossible for children to get at or into the medicine closet. Leave nothing about by which children can possibly get poisoned or injured. Never drink or take ANYTHING in the dark! Never guess at the character of a substance! Find out what it is before you use it, or let it alone. Never use tablets or capsules left lying about loose without proper container and label. Look twice at everything you use from a bottle or medicine box. Use your nose, and your eyes, and not your tongue.—C. E. Vail.

REAL FOOD VALUE IN SALADS

Some people think that salads are an extravagance, time killers, and generl nuisances. However, if the food value of salads is properly appreciated, their use will not be confined to company dinners and Ladies' Aid meetings.

In the first place, any salad dressing contains a considerable amount of fat. Usually, there is an accompaniment of herbs, as lettuce or water cress, that furnish valuable mineral constituents, as well as giving bulk.

For the materials for the main part of the dish, there are many to choose from. If the meal has been heavy, fruits, furnishing water and minerals, might well be chosen. If the rest of the meal is light, the more nutritious animal or vegetable foods may be used, e.g., meats, shell fish, eggs, nuts, cheese, or vegetables, either raw or cooked.

A salad is a many-sided dish, in that it usually includes some of all the food principles. There is contrast in texture, flavor, and color. The appearance of a salad may be a decided stimulant to the appetite.

Also, salads are just as valuable for the man doing heavy work, as they are for his wife, and they will not make him into a monocled, wrist-watched mollycoddle. Try them and see.—Magdalene Hahn, Colorado Agricultural College.

It used to be that girls were taught housekeeping and that was considered enough. Today, throughout the land, people are waking up to the tremendous importance of studying homemaking as well. It it not an idle sentiment, but a fact, that one's personality, as well as his daily happiness, is molded to a large extent by his environments. And it follows that in homes the members are responsible for this environment as it is.

True, that a home without love would be a poor imitation of a home, and no amount of harmony in color schemes will atone for lack of harmony in family life. But it is also true that a room by its mere furnishings and the arrangement of them can do much to insure content or discontent; to make the inmates cheerful or discouraged, optimistic or depressed. And that is why a woman's duty as a homemaker does not end in giving her family bodily comforts, nor yet even in an abundance of love.

BURDOCK BLOOD BITTERS WILL MAKE YOU EAT.

The sufferer from dyspepsia and indigestion who has to pick and choose his food, is the most miserable of all mankind.

Even the little he does eat causes such torture, and is digested so imperfectly that it does him little good.

What dyspeptics need is not artificial digestion but something that will put their stomach right so it will manufacture its own digestive ferments.

Burdock Blood Bitters restores the stomach to a normal, healthy condition so that food no longer distresses, but is thoroughly digested and assimilated.

Miss Ella McDonald, Charlottetown, P.E.I., writes: "I have used Burdock Blood Bitters, and find that few medicines can give such relief in dyspepsia and stomach troubles. I was troubled for three years with dyspepsia and could not get anything to do me any good until I took B.B.B. I took four bottles, and I can honestly say I am now cured, and can eat anything without it hurting me."

B.B.B. is manufactured only by The T. Milburn Co., Limited, Toronto, Ont.

LABOR DAY EXCURSION TO THE EXPERIMENTAL FARM, FREDERICTON

At the last annual meeting of the Farmers' and Dairymen's Association a resolution was unanimously carried that the Association should have an excursion to the Experimental Farm, Fredericton, during the present summer.

As the season has been very late, the officers felt that it would not be satisfactory to the member or their visitors to visit the farm before the crops were large enough for inspection, nor did they think the date should come during the haying season. The date has therefore been fixed for LABOR DAY, MONDAY, SEPT. 3rd.

An interesting programme will be provided, including short addresses from J. H. Grisdale, Director Experimental Farms; Hon. J. F. Tweeddale, N. B. Minister of Agriculture, and other prominent agriculturists to be later announced. Demonstrations in Spraying, Potato Digging, etc., with talks on diseases of plants and other matters, will be given by G. C. Cunningham, Dominion Plant Pathologist. Live Stock demonstrations by Thomas Hetherington, Provincial Live Stock Superintendent, and an opportunity will be given to inspect all departments of the farm, machinery, etc.

It will be time and money well spent for farmers who are interested in potato growing to visit the Experimental Farm, and carefully note the experiments that are being there conducted this season by Prof. Cunningham. It will mean that they will pay more attention to the seed they use better care of the growing crops, and more money in return on their labors.

Lunch will be provided from eleven to one o'clock.

If Labor Day Excursion Return Tickets cannot be bought at single fare, buy a single first class ticket for Fredericton and secure a Standard Certificate.

On arrival at the Farm, excursionists will register their name and address with the Secretary and get their Standard Certificates signed when they will be given a ticket admitting them to the Lunch Room.

Go and take your friends.

Ladies are especially invited.

IMPROVISED SHEDS FOR TOOLS

We used to leave our manure spreader out in the open, simply because we used it often and had no room in the main barn for it. Now, it has a cozy little shed all by itself, giving it full protection from the weather and still making it readily accessible.

A few poles from the woods, a few posts, some boards that were scattered about the premises and rotting to pieces, some discarded tin roofing from another building, and a few hours' time, were all that were required. The material had been on hand for years, yet we had never thought to use it.

Recently we completed a similar shed, improvised and cheap, but mighty serviceable. In it we have the binder, hayloader and a lot of smaller tools. Built against the wagon shed, we had one side of the shed already constructed, while for the other side we used three idle hog coops. Carefully arranged bundles of fodder inclose the ends. The top was made from old tin roofing. It cost very little and is saving us a lot.—P. C. Grose.

CARE OF MACHINERY

Failure to properly lubricate the working parts of the various machines used in farm work is the source of much loss to farmers. Under such conditions there is undue wear and tear and an early trip to the junk heap. One man neglected to fill a grease cup on his tractor and he had to pay a repair bill of $125 as a consequence. Just now when the mower, the binder, the hay loader and other tools that have many bearings and that run rapidly are in use one cannot be too careful about proper oiling. There isn't a doubt but that the life of a machine can be lengthened many years by proper lubrication.

A DOUBLE SERVICE

War Certificates Help You and Help the Country

By saving twenty-one dollars and fifty cents you can contribute directly to victory. War Savings Certificates are on sale at your nearest bank or money order post office. They are issued in three amounts, for three year periods and bear interest at the rate of over 5 per cent. Twenty-one dollars and fifty cents will buy you a $25 certificate. You can buy a $50 one for $43 and a $100 for $86. The country needs your money to finance the war. It is spending nearly $2,000,000 a day to maintain its divisions on the firing line and keep up the proud record of the Dominion. Every dollar that can be spared is required to carry that burden. By lending your money to the nation you will place it where it can be used for national purposes and you will help yourself as well as help the man in the firing line. The certificates are registered at Ottawa. They cannot be lost. The return is good, the security unquestioned. Invest your dollars and help to win the war.

WASTE NO FAT—SUGGESTIONS FOR ITS UTILIZATION

At this time when all kinds of fats cost so much, it behooves the thrifty housewife to utilize every bit that comes into the kitchen.

The fat from mutton or lamb may be used in maying soap, or in making tallow that is good for chapped hands.

Goose grease is an old-time remedy for sore throats.

Chicken-fat, rendered, makes an excellent cooking fat. It is especially good for biscuits, cornbread, muffins, or spice cakes.

Beef fat or suet, is much cheaper than lard and can in most cases, be substituted for it.

Any fat from pork can be rendered and used in cooking. When trimming meat at home, save all fat and render it. If the meat is trimmed at the market, insist on having the trimmings delivered with the meat.

The unrendered rind that is cut from meat makes an excellent grease for griddles, skillets, or other pans. Whn cooking bacon, pour off the excess fat and save it. It is very good for browning potatoes or parsnips.

The cracklings that remain when fat is rendered may be used in soap, corn breads, spice cake or for chicken feed.

Any butter that is not fresh may be worked over with cold water and greatly improved.

Rancid olive oil can be freshened by heating with a few slices of potato.—Magdelene Hahn, Colorado Agricultural College, Fort Collins, Colo.

Two Cents a Word.

This department is one of the most valuable in the MARITIME FARMER. At a cost of only 2 cents a word, you can advertise anything you wish to buy, sell or exchange. The adress must be counted as part of the advertisement and each initial or a number counts as one word. Cash must accompany each order and advertisement must have address on, as we cannot forward replies sent to this office. Copy must be received not later than Friday before the date of issue which will always be found on the editorial page of the proceeding issue. No black faced type or display of any kind will be allowed under this head, thus making a small add as noticeable as a large one. The rate for this column is 2 cents a word, each insertion. Fir Shade Farm Dual-Purpose Shorthorns !

Several years ago I imported from Ontario three Dual-Purpose Shorthorn animals, and now have in my stable at Rothesay eight representatives of this breed. Two of the females are entered in the Record of Performance, and so far have done excellent work. If you feel disposed you might drop in and see these the first time you are in the vicinity. Perhaps some time when you are coming to the city you would let me know, when I could arrange to go to Rothesay with you.

P. R. L. FAIRWEATHER. St. John, N. B.

FOR SALE

A handsome, well-grown Guernsey bull. Sire purchased from the Experimental Farm, Ottawa; dam of equally good breeding, and a heavy producer. Will be sold reasonable. Full particulars on inquiry.

SARAH E. MOSES SMITH,
Woodwards Cove, - - - N. B.

BUTTER PARCHMENT
Printed or Plain, at the Maritime Farmer Office

SHOW STOCK SALE!

"Minnie Vale of Victoria," another four year old daughter of "Ida Rooker 2nd Vale," has just finished a R.O.P. record of 15.784 lbs. milk and 5.61 lbs. fat, making two daughters in R.O.M. and R.O.P., all showing a much higher milk and fat record than dams. He is also a breeder of show type as proved by his continual winnings in the (get of sire class) at all Maritime Shows.

We can sell a few grand young Bulls by him, different ages, also expect to have a show lot of P. B. and grade females at Halifax, several choice ones to freshen then.

Drying Fruits & Vegetables in the Home

"Can, Preserve, Dry and Store" Advises the Canadian Food Controller

The United States Department of Agriculture has issued a bulletin giving the following information about drying of fruits and vegetables.

Reasons for Drying Fruits and Vegetables

One of the most important features of the food conservation programme of European countries has been the universal drying of fruits and vegetables. The surplus vegetables in the city markets were forced by the Governments into large municipal drying plants. Community driers were established in the trucking regions and even itinerant drying machines were sent from farm to farm drying the vegetables which otherwise would have gone to waste. In addition, large quantities of dried vegetables from Canada and this country were shipped to France during the last two years, and there is a possibility that dried fruits and vegetables may continue to be shipped abroad in considerable quantities to supplement the concentrated food diet of the men in the trenches.

The drying of vegetables may seem strange to the present generation, but to our grandmothers it was no novelty. Many housewives even to-day prefer dried sweet corn to the product canned by the old method and say also that dried pumpkin and squash are excellent for pie-making. Snap beans often are strung on threads and dried above the stove. Cherries and raspberries still are dried on bits of bark for use instead of raisins. In fact, many of the everyday foodstuffs already are dried at some stage of their preparation for market. The common dried fruits, such as prunes, raisins, figs, dates, and apples are staples in the world's markets, while beans and other legumes, tea, coffee, cocoa, and various manufactured foods, like starch, tapioca, macaroni, etc., are dried either in the sun and wind or in specially constructed driers.

Even though the drying of fruits and vegetables as practiced a few decades ago on many farms has become practically a 'lost art", the present food situation doubtless will cause a marked stimulation of drying as a means of conserving the food supply. This country is producing large quantities of perishable foods this year, which should be saved for storage, canned or properly dried. Drying is not a panacea for the entire waste evil, nor should it take the place of storing or canning to any considerable extent where proper storage facilities are available or tin cans or glass jars can be obtained readily and at a low cost.

The advantages of drying vegetables are not so apparent for the farm home as they are for the town or city household, which has no root cellar or other place in which to store fresh vegetables. For the farmer's wife the new methods of canning probably will be better than sun drying, which requires a somewhat longer time. But shorter methods of drying are available, and the dried product holds an advantage in that usually it requires fewer jars, cans, or other containers than do canned fruits or vegetables; also dried material can be stored in receptacles which cannot be used for canning. Then, too, canned fruit and vegetables freeze and cannot be shipped as conveniently in winter. Dried vegetables can be compacted and shipped with a minimum of risk.

To the housewife in the town the drying of vegetables and fruits presents special advantages. During the season when the market is oversupplied locally and prices are low she can lay in a stock dry it, and put it away for a winter's emergency without its taking up much of the needed small storage space in her home. If she is accustomed to canning her fruit and vegetables and finds she cannot secure jars or tin cans, she can easily resort to drying.

With simple and inexpensive facilities, all housewives can save quantities of food which are too small conveniently to can. A few sweet potatoes or apples or peas, or even a single turnip can be dried and saved. Even when very small quantities are dried at a time, a quantity sufficient for a meal will soon be secured. Small lots of several dried vegetables, such as cabbage, carrots, turnips, potatoes, and onions, can be combined to advantage for soups and stews.

This bulletin records some of the points brought out in a preliminary investigation of the home drying of fruits and vegetables which has been conducted by the department.

Principles and Methods of Drying

Three main ways of drying are applicable in the home manufacture of dried frulits and vegetables, namely, sun drying, drying by artificial heat, and drying by air blast. These, of course, may be combined. In general, most fruits or vegetables to be dried quickly, must first be shredded or cut into slices, because many are too large to dry quickly or are covered with skin, the purpose of which is to prevent drying out. When freshly cut fruits or vegetables are to be dried by means of artificial heat, they should be exposed first to gentle heat and later to the high temperatures. If the air applied at the outset is of too high a temperature, the cut surfaces of the sliced fruits or vegetables become hard or scorched, covering the juicy interior so that it will not dry out. Generally it is not desirable that the air temperature in drying should go above 140° to 150° F., and it is better to keep it well below this point. Insects and insect eggs are killed by exposure to heat of this temperature.

[illegible] of heat in the drier, and this cannot be determined very accurately except by using a thermometer. Inexpensive oven thermometers can be found on the market, or any ordinary chemical thermometer can be suspended in the drier. If a thermometer is not used, the greatest care should be given to the regulation of the heat. The temperature in the drier rises rather quickly and the product may scorch unless close attention is given. The reason sun drying is regularly believed to give fruits and vegetables a sweeter flavour lies probably in the fact that in the sun they never are scorched, whereas in the oven or over a stove scorching is likely to occur unless careful attention is given them.

Drying of certain products can be completed in some driers within two or three hours. The time required for drying vegetables varies. However, it can be determined easily by a little experience on the part of the person doing the drying. The material should be stirred or turned several times during the drying in order to secure a uniform product.

The ability to judge accurately as to when fruit has reached the proper

Fig. 1.—Meat grinder used for making cooked potato into strings, dropped directly into a tray for drying.

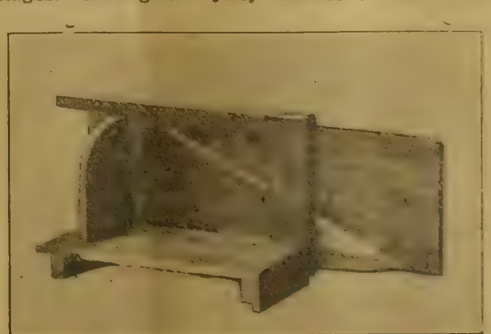

Fig. 2.—A fruit slicer of this type can be used for slicing or shredding the large vegetables or fruits.

Fig. 3.—A rotary slicer being used to cut string beans into small pieces.

Fig. 4.—The same rotary slicer as shown in fig. 3, being used to cut sweet potatoes into slices and then into strips, dropping them on to the tray, ready to dry.

but convenient and inexpensive machines which can be used to great advantage are on the market. The meat grinder (fig. 1) with its special discs can be used in certain cases; the common kraut slicer (fig. 2) will cut large vegetables into thin slices, such as potatoes and cabbage; and the rotary hand slicer shown in figs. 3 and 4 is adapted for use on a very wide range of material. A large kitchen knife may be used when a handier cutting device is not available. Care should be taken that the material is sliced thin enough but not too thin. From an eighth to a quarter of an inch is a fair thickness for most of the common vegetables to be sliced and dried. Very small slices or strips dry more quickly because they expose a greater surface to the air than do larger cut pieces. But if cut too fine they are more difficult to handle in drying, appear to lose somewhat in flavour, and cannot be used so advantageously to make above, nicks off the outer skin and leaves only the eyes to be dug out.

Blanching of vegetables is considered desirable by some housekeepers, although it is not strictlf essential to successful drying. It is claimed that the blanch gives a more thorough cleaning, removes the strong odour and flavours from certain kinds of vegetables and softens and loosens the fibre. This allows the moisture in the vegetable to evaporate more quickly and uniformly. It also quickly coagulates the albuminous matter in the vegetables which helps to hold in the natural flavours. Blanching consists of plunging the vegetable into boiling water for a short time. Use a wire basket or cheesecloth bag for this. After blanching the required number of minutes, drain well and remove the surface moisture from vegetables by placing between two towels or by exposing to the sun and air for a short time.

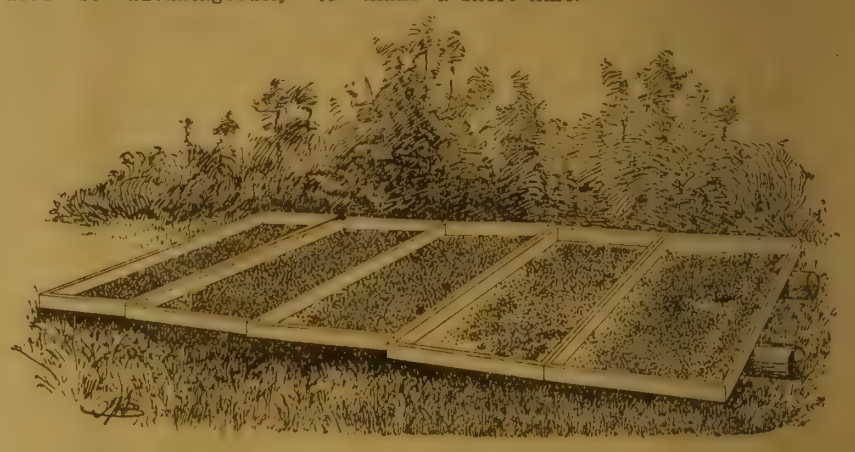

Fig. 7.—Trays used for drying fruits and vegetables in the sun.

condition for removal from drier can be gained only by experience. When sufficiently dried it should be so dry that it is impossible to press water out of the freshly cut ends of the pieces and will not show any of the natural grain of the fruit on being broken, and yet not so dry that it will snap or cackle. It should be leathery and pliable.

When freshly cut fruits or vegetables are spread out they immediately begin to evaporate moisture into the air around them, and if in a closed box will very soon saturate the air with moisture. This will slow down the rate of drying and lead to the formation of moulds. If a current of dry air is blown over them continually the water in them will evaporate steadily until they are dry and crisp. Certain products, especially raspberries, should not be dried hard, because if too much moisture is removed from them they will not resume their original form when soaked in water. On the other hand, the material must be dried sufficiently or it will not keep, but will mould. Too great stress cannot be laid upon this point. This does not mean that the product must be baked or scorched, but simply that it must be dried uniformly through and through.

It will be found advisable also to "condition" practically all dried vegetables and fruits. This is best done in a small way by placing the material in boxes and pouring it from one box into another once a day for three or four days so as to mix it thorughly and give to the whole mass an even degree of moisture. If the material is found to be too moist it should be returned to the drying trays for a short drying.

Fig 5.—This type of potato peeler removes the skins quickly, leaving the eyes to be removed with a sharp pointed knife.

Preparation of Food for the Drier

In large factories vegetables are put through special shredders and slicers not adapted for home use, dishes like those prepared from the fresh foods.

The slicing machines (figs. 2, 3, 4) are not suitable for children's use, for they will cut fingers as mercilessly as they do vegetables and fruits, and even adults should exercise great caution in their use in the home.

Cleanliness is as necessary in the preparation of vegetables and fruits for drying as in their preparation for canning, perhaps even more so. To secure a fine quality of dried produce much depends upon having the vegetables absolutely fresh, young, tender and perfectly clean. If steel knives are used in paring and cutting have them clean and bright so as not to discolour the vegetable. The earthy smell and glavot will cling to the root crops if they are not washed thoroughly before slicing, and one decayed root may flavour several kettles of soup if the slices from it are scattered through the whole batch of dried material. High-grade dried "root" vegetables can only be made from peeled roots.

In preparation of large quantities of potatoes a potato peeler such as shown in figs. 5 and 6 may be utilized. The potatoes are thrown by centrifugal force against a rough surface which, under streams of water provided by the perforated tin container

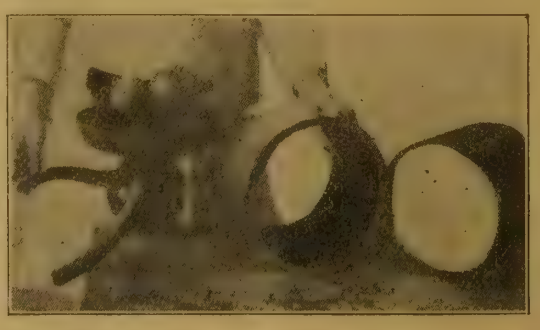

Fig. 6.—Potato peeler taken apart, showing the receptacle (right) which holds the water and the rough-walled chamber (centre) which removes the peel.

Apparatus for Drying

The drying of fruits and vegetables in the sun is a simple process if they have been prepared properly. In its simplest form such drying consists in spreading the freshly prepared slices or pieces on sheets of paper, or, if there is danger of the product's sticking, spreading on old pieces of muslin held down with stones. Bright hot sunny days are chosen for this work, and a close watch is kept to see that no rain or dew wets the product. If flies and other insects are abundant, a mosquito bar is thrown over the product. Once or twice a day the slices are stirred or turned over with the hand and the thin ones which dry first are taken out. Sun drying has much to recommend it, since it requires no expenditure of fuel and there is little danger of the product becoming overheated. Dust, however, gathers on the product, and unless it is protected carefully flies and especially certain insects which habitually attack dried fruits will lay their eggs upon it. These eggs later will hatch out and the worms or larvae will riddle the dried fruits or vegetables, rendering them unfit for the table.

Fruits and vegetables, when dried in the sun, generally are spread on large trays of uniform size (fig. 7), so constructed that they can be stacked one on top of the other and protected from rain by means of a cover made of oilcloth, canvas or roofing paper.

A very cheap tray can be made of strips of lumber three-fourths of an inch thick and two inches wide, which form the sides and ends, and lath which is nailed on to form the bottom. Spaces one-eighth inch wide should be left between the laths for ventilation and the trays can be raised off the ground by placing them on poles or an improvised trestle. As laths are four feet long, these lath trays are the most economical of material when made four feet in length.

Fig. 8.—A homemade drier made of lath and wire netting. It can be swung over the stove or back out of the way. Although not shown in the illustration, trays are made to fit into the wire and lath shalves The lath crane is fastened to the wall by means of a hinge made of a turn of wire with a loop in it which is bent around the upright. The looped wire is hung on nails which are driven into the wall and then bent upward at right angles.

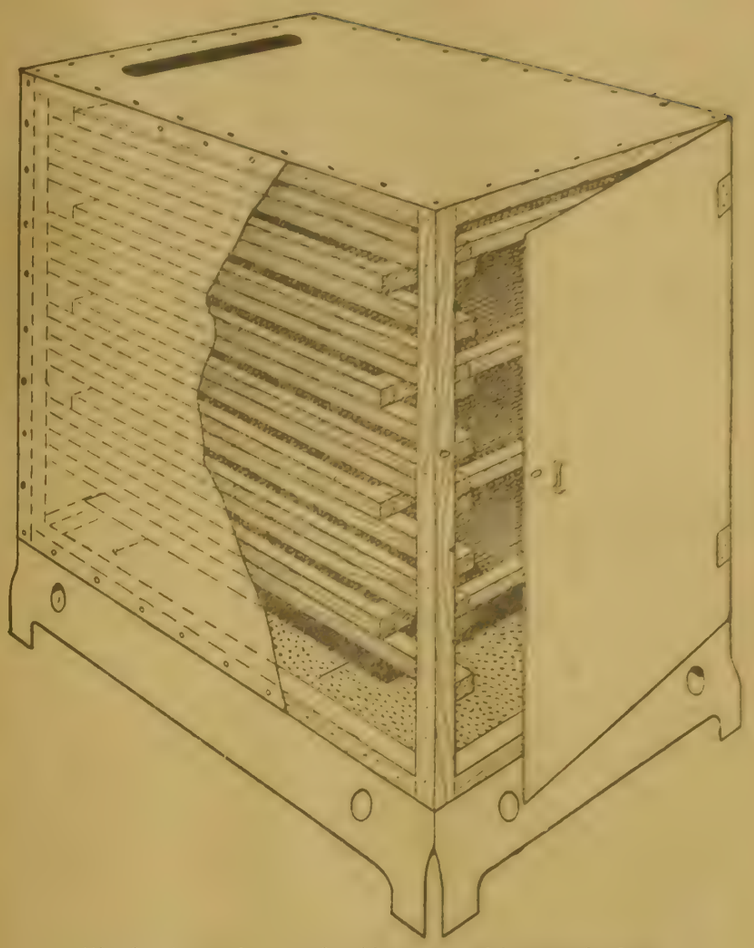

Fig. 9.—A metal covered cabinet type of homemade drier.

Better but more expensive trays can be made by substituting galvanized-wire screen, one-eighth or one-quarter inch mesh, for the laths, in which case the most economical size would depend upon the widths of the wire screen obtainable.

A cheap and very satisfactory drier (fig. 8) for use over the kitchen stove can be made by any handy boy or carpenter from a small amount of small-mesh galvanized-wire netting and a number of laths or strips of wood about one-half inch thick and two inches wide. The screen may be tacked directly on the framework to make the drying shelves, or the framework can be made to support separate trays. By using two laths nailed together the framework can be stiffened and larger trays made if desirable. This form or any of the lighter makes of driers can be suspended from the ceiling over the kitchen range or over the oil, gasolene or gas stove, and it will utilize the hot air which rises during the cooking hour. It can be raised out of the way or swung to one side by a crane made of lath (fig. 8) when the stove is required for cooking purposes, and lowered or swung back to utilize the heat which otherwise would be wasted when the top of the stove is not in use.

Fig. 10.—A patented drier to be used on the kitchen stove. It has a chamber inclosing the trays and is ventilated by a flue.

Another homemade cookstove drier that can be used on a wood or coal range or a kerosene stove can be made easily and cheaply (fig. 9). Dimensions: Base 24 by 16 inches; height 36 inches. A base 6 inches high is made of galvanized sheet iron. This base slightly flares toward the bottom and has two small openings for ventilation in each of the four sides. On the base rests a boxlike frame made of 1 or 1½ inch strips of wood. The two sides are braced with 1¼ inch strips which serve as cleats on which the trays in the drier rest. These are placed at intervals of 3 inches. The frame is covered with tin or galvanized sheet iron which is tacked to the wooden strips of the frame. Thin strips of wood may be used instead of tin or sheet iron. The door is fitted on small hinges and fastened with a thumb latch. It opens wide so that the trays can be removed easily. The bottom of the drier is made of a piece of perforated galvanized sheet iron. Two inches above the bottom is placed a solid sheet of galvanized iron which is 3 inches less in length and width than the bottom. This sheet rests on two wires fastened to the sides of the drier. This prevents the direct heat from coming in contact with the product and serves as a radiator to spread the heat more evenly.

The first tray is placed 3 inches above the radiator; the trays on the cleats 3 inches apart. A drier of the given dimensions will hold 8 trays. The frame of the trays is made of 1 inch strips on which is tacked galvanized screen wire. which forms the bottom of the tray. The tray is 21 by 15 inches, making it 3 inches less in depth than the drier. The lowest tray when placed in the drier is pushed to the back, leaving the 3 inch space in front. The next tray is placed even with the front, leaving a 3 inch space in the back. The other trays alternate in the same way. This permits the current of heated air to pass around and over the trays. A ventilator opening about 2 inches wide and 6 inches long is left in the top of the drier, through which the moist air may pass away.

This principle of construction is followed so that currents of heated air will pass over the product as well as up through it, gathering the moisture and passing away. The movement of the current of air induces a more rapid and uniform drying. The upper trays can be shifted to the lower part of the drier, and the lower trays to the upper part as drying proceeds, so as to dry the products uniformly throughout.

Still another home drier is the

Fig. 11.—The same drier as in Fig. 10, open to show the parts.

cookstove oven. Bits of food left over, especially sweet corn, can be dried on plates in a very slow over or on the back of the cookstove and saved for winter use. If the oven is very warm the door should be left ajar and the temperature of the oven noted. Trays for use in the oven can be made from a convenient sized galvanized wire screen by bending up the edges 1 or 2 inches.

Cookstove driers on the market are of two types. One type (figs. 10-12) consists of a series of trays upon which the material to be dried is spread. These trays are placed in a framework one above the other, forming a compartment through which the heated air rises carrying off the moisture. The second type (fig. 13) consists of a shallow flat metal box filled with water and designed so that one end can rest on the back of the stove and the other on a leg reaching to the floor. It also may be supported over a lamp. The use of an electric fan for facilitating drying is shown in figure 14. This is feasible for those who already own a fan. It has been found that many sliced vegetables and fruits placed in long trays 3 by 1 foot and stacked in two tiers, end to end, before an electric fan can be dried to the requisite dryness within 24 hours. Some require much less time. For instance, sliced string beans and shredded sweet potatoes will dry before a fan running at a moderate speed within a few hours. In many cities the electric fan will cost not more than one-fourth of a cent an hour to run. The fan should be placed close to the stack of trays, and they should not be filled so full that the air cannot pass freely through them. The fan method has a marked advantage in that the product keeps cool owing to evaporation while it is being dried, thus tending to retain the colour and eliminate spoilage.

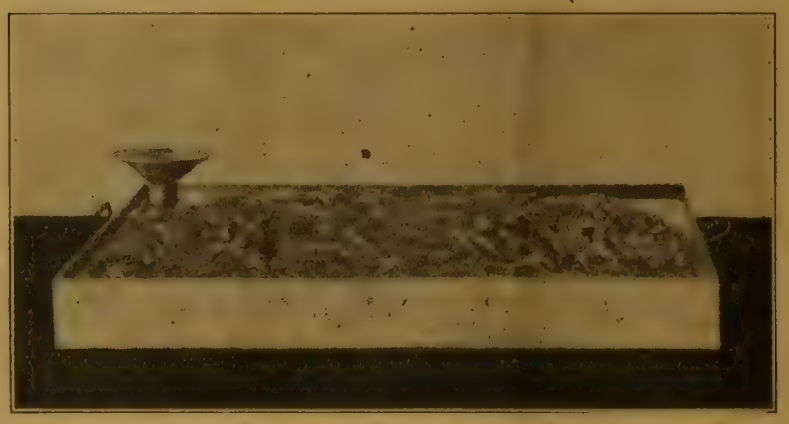

Fig. 13.—This patented drier made of a metal box filled with water, may be set on the edge of the stove or it may be supported over a lamp.

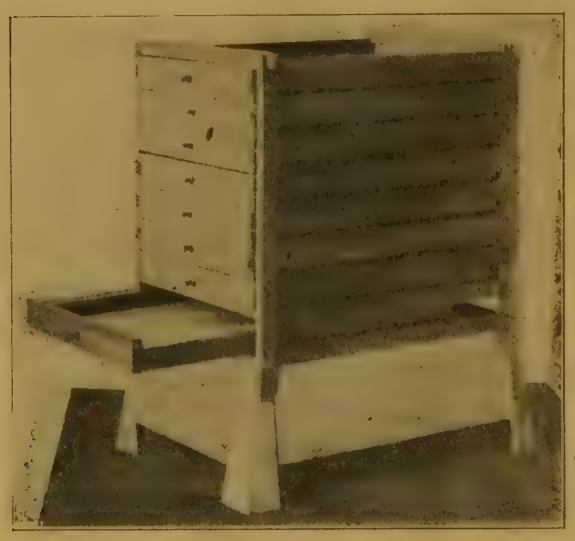

Fig. 12.—Another patented drier designed to be set on the kitchen stove, the hot air rising through the trays.

The N.B. Farmers Excursion to Experimental Station

Every practical, progressive farmer conducts experiments from time to time on his own farm, to prove the advantages or disadvantages of the respective phases of his family operations. He tries and proves ideas that may originate in his own mind, or perhaps ideas that he may have gleaned from his fellow farmers, or that are conveyed to him through the press.

The progressive farmer is on the qui vive for any ideas that will shorten his work or increase the returns for his labors—ideas that will not only benefit himself but also the generations that are to follow.

All over Canada we find farmers of this class, and we are pleased that the Maritime Provinces can claim a host of them.

Experimentation in many instances costs a lot of time and money—perhaps more than the average farmer can afford. If the idea is one that, when tried, is not found wanting, both time and money expended is well spent. On the other hand, if the idea is not a feasable one, the time and money expended is wasted.

When a large number of farmers, separately conducting unworkable ideas, or ideas that will not prove of any practical value, even if put in practice, the waste of time, money and energy is enormous.

When one or more farmers test an idea and it is found practical—it may be money making or labor saving—frequently the results of the experiments conducted are not given to the public as quickly as their value would warrant. The work proceeds slowly until gradually the information is passed from neighbor to neighbor, until finally it comes to the attention of some one who will give it merited publicity.

To facilitate the work of experimentation, the Dominion Government established a system of Experimental Farms, Stations and Sub Stations, where ideas of all kinds and in all branches of the Agricultural Industry is put into practice, and an annual report of the results is published and distributed free of cost to the public.

The practical farmer of today, while conducting some inexpensive experiments for himself, allows the Experimental Farms to do the work for him. They are better equipped for the work and have more time and money at their disposal than he has.

A few years ago an Experimental Station of this kind was established near Fredericton to serve a large portion of the Province of New Brunswick. Mr. W. W. Hubbard, at one time Editor of The Maritime Farmer, and later Secretary for Agricultre for the Province of New Brunswick, was placed in charge. Farmers who knew the conditions existing on the newly purchased farm, and who have had an opportunity to witness the progress that has been made up to the present time, are best able to judge of the energy and effectiveness Mr. Hubbard has put into his work. Many waste places on the farm have been cleared and are now producing crops, and the whole area is being worked up to the stage where demonstrations of practical value are being and will be put into effect.

One may read a great deal and glean much practical information, but the most practical system of instruction is "learning by doing, and by seeing things done". This system is now recognized the world over.

The New Brunswick Farmers and Dairymen's Association, alive to this fact, instituted an annual excursion to the Experimental Farm, Fredericton. Their initial attempt in 1916 was a decided success, and when we say that this year farmers and others interested in agriculture to the number of nearly 3000, congregated there on September 3rd, Labor Day, when all labor was suspended, will readily agree with us that the excursion was successful beyond the most sanguine expectations of the officers of the Association.

All trains coming to Fredericton that day, brought in large numbers of farmers and their families. Long processions of carriages and autos dotted the highways, and they were all heading towards the Experimental Station.

The weather was all that could be desired. Dinner was served by the ladies of the Fredericton Women's Institute to upwards of 1300 people. Others brought their baskets, and the remainder who were not lucky enough to gain an entrance to the dining hall, had to go hungry. Suffice to say, that dinner was served as expeditiously as possible. As many as could be accommodated were looked after. There was not a moment to spare from the time the first excursionists arrived, until the last train pulled out.

It was a busy day for Chas. N. Shaw, The Recording Secretary; A. R. Wetmore, The Corresponding Secretary, and H. H. Smith, the Treasurer, who had charge of registering the delegates, filling in the Standard Certificates and issuing admissions to the dining hall.

The president of the Association, Mr. Isaac Baird, was also on hand to introduce the various speakers who addressed the large audience on the green.

W. W. Hubbard, the Superintendent of the Station, on being introduced, heartily welcomed the farmers. He was pleased with the idea of a Farmers' Field Day. He referred to the development ideas that are being put into practice on the Experimental Farm. From an area of 60 acres, the land fit for use has been extended to the 250 acres now under crop. He then as a guide to the visitors, explained the various departments of the farm and where they might be found.

The Minister of Agriculture was the next speaker. Mr. Tweeddale, who is a practical farmer, knows full well the various needs of his fellow tillers of the soil, and as such is in a position to help them. He has imbued the various members of his staff with the idea that agriculture is too big and important a matter to be played with for political purposes. His aim is to make his Department of practical, efficient service to every agriculturist in the province, regardless of their political affiliations, color or creed. In order that the department may be brought in close touch with the farmers, he advised every farmer to join his nearest Agricultural Society, or if there is not one within easy reach, one may be organized in any district where twenty-five or

(Continued on page 583)

THE WORLD'S WHEAT SITUATION

By N. C. Murray of the U. S. Bureau of Crop Estimates

The wheat crop of the world in a recent year has averaged somewhat more than 3¾ billion bushels and is produced from about 275 million acres. Three and three-quarters billion bushels would fill a cubic space measuring about 555 yards each way.

The average yield per acre of wheat for the whole world is a little above 13.5 bushels, the range between poor and good crop years being approximately between 13 bushels and 15 bushels. In England and the Netherlands the average yield per acre exceeds 33 bushels while in Russia and North African countries the average yield falls below 10 bushels per acre. Wheat tends to increase in yield per acre the farther one goes along the same longitude from the warmer to the cooler latitudes, until one reaches near the limits of its production. Thus the average yield per acre of winter wheat is larger in Ontario than in Ohio, larger in Ohio than in Kentucky, larger in Kentucky than in Tennessee. In Europe yields are larger in all northern countries than in southern countries. Even in England yields are larger in the northern than in the southern countries. In India, too, yields are larger in the northern than in the southern provinces. In the southern hemisphere, in Argentina, largest yields are in the southern provinces and smallest in the northern provinces, and the yields in New Zealand are much larger than in any part of Australia proper. This fact should be taken into consideration when comparing yield of one country with that of another. In countries where both winter and spring wheat are grown, the average yield of winter wheat is almost invariably larger than that of spring wheat. Less than one-third of the crop grown in the northern hemisphere is spring wheat, and more than two-thirds is winter.

In practically every important wheat-growing country the average yield per acre is steadily increasing, even in countries where the present yield is high. Thus, in England the average yield has increased from 31.2 bushels in the decade from 1890 to 1899 to 33.1 bushels in the next decade, an increase of 6 per cent in ten years.

During the past twenty-five years world production of wheat has been increasing more rapidly than the population. Wheat production since 1890 has been increasing at the average rate of about 2½ per cent. a year, while population has been increasing but little more than 1 per cent a year. The result of this development of production faster than growth of population has been an extension of wheat consumption among people who did not use it before, and an increase of per capita consumption among the principal wheat consuming nations. Statistics of production, imports and exports, taken in conjunction with population, indicate that the per capita consumption of wheat in recent years (before the war) was greater than thirty or forty years ago.

The war broke out at a time when the world was bountifully supplied with wheat as well as other foodstuffs. The wheat crop of 1913 was the largest that had ever been produced and the 1914 crop was above average. That is two large crops in succession preceded the outbreak of the war. The second year of the war was maintained from the crops of 1915.

The first results of the war of importance in the wheat situation were the closing of the Dardanelles, preventing exportation of Russian and Danubian wheat, and the victory of the Allies on the high seas—at that time ths submarines were not a serious menace. The closing of the Dardanelles, preventing the exportation of Russian and Danubian wheat and caused increased demand from other countries. This situation stimulated acreage, particularly in the neutral countries, and the season of 1915 happened to be unusually favorable for large yields. Hence the world wheat crop of 1915 was enormous—over 4½ billion bushels. A reversal came in 1916, in short, the 1915 crop was enormous and the 1916 crop was relatively short.

The present world wheat situation cannot be regarded as particularly encouraging, neither is it positively discouraging. We are nearing the close of the crop season of 1916 with low reserves and with only moderate prospects for the new (coming) crop. The United Kingdom, which is the largest wheat importer, has only fair prospects. She produces only about one-fourth of her needs. Under normal conditions she requires abut 230 millin bushels from exporting countries, vantage this much during the coming season. No information is available as to present stocks in England, as such news is censored, but it may be presumed that conditions are such as necessitate the conserving of whatever supplies are on hand. France normally produces about 325 million bushels of wheat and imports about 40 millions. Her production last year was moderately over 200 millions—a material shortage. Prospects are for little, if any increase over last year. The other European importing countries' prospects for the coming crop are not better than average, and their demand during the year may be expected to be equal to or greater than their normal demand.

Russia is normally a large surplus producer, exporting normally about 120 million bushels per year. It might be presumed, therefore, that the cutting off of this export business might result in large accumulations of wheat in that country; but this is problematical. The International Institute of Agriculture reports the visible stocks of wheat in Russia as unusually low—only about three million bushels last December, as compared with nearly 20 millions in December, 1915.

THE GUARANTEE of quality that goes with every package of KING COLE TEA, is as binding to-day as it was in days before the war.

It COMPELS us to give the same exacting care in the selection and blending of teas used in each grade of KING COLE.

THE GUARANTEE is plainly printed on every KING COLE package and it is the most positive assurance of high quality that the buyer can possibly have, for it provides redress if for ANY reason there should be dissatisfaction.

The different grades of KING COLE TEA are:—

Crimson Label	- Today's Retail price	55c.
Green Label	" " "	60c.
Blue Label	" " "	65c.
Gold Label	" " "	75c.
King Cole Orange Pekoe	" " "	70c.

Prices may change up or down owing to market conditions but the QUALITY of each grade must be maintained at the same ORIGINAL STANDARD.

G. E. BARBOUR COMPANY, LIMITED
ST. JOHN, N. B.

THE GREATEST ERROR IN FEEDING THE DAIRY COW IS LACK OF LIBERALITY

Little attention has been given heretofore to dairying in its relation to the farm as a whole, or in its ecthe fact that much attention has been devoted to methods of production, feeding and care. What dairy farmers must come to appreciate is the actual value of determining the cost of production in detail, and the relation of that cost to the product and income therefrom. The object should be to show the exact status of the dairy industry and the cost of dairy products to the producer, endeavoring to reduce therefrom the economic principles that govern the dairy industry.

Factors entering into the cost of producing milk, though consisting of many different items, may be definitely divided into the following classes; Labor of man and horse, feeds, depreciation, cost of shelter, general expense, interest on investment, and use of machinery in equipment. These factors represent the actual cost of the maintenance of a herd on a dairy farm.

Figuring Labor Costs

The two classes of labor used in the dairy business are man labor and horse labor. In cost data all labor performed in the care of cattle should be charged to that enterprise at current rate of wages. This rate is based upon the employment of hired men, and is obtained by dividing the aggregate monthly wages paid, plus the aggregate cost of board by the aggregate number of hours' work performed each month. This gives a base figure of cost per hour upon which all wages are calculated for any enterprise.

The cost of feed contributes to the cost of maintenance and to the final cost of the product. Low prices for roughage and concentrates and high prices for product means profit; while with high-priced food stuffs and low prices for product profits are materially lessened.

The farm price of farm-grown feeds is the market price, less the cost of transportation from the farm to the nearest market. To illustrate: If barley is forty-five cents per bushel at the market where the farmer sells his grain and the cost of transportation from the farm to the market is one and a half cents a bushel, the farm price would be forty-three and a half cents per bushel. However, when roughage or concentrates are purchased, the cost of hauling to the farm is then charged to the cost of maintenance of the stock to which it is fed.

Value of Farm Feeds

When feeds have no market price, as is frequently the case with corn fodder, millet hay, root crops, silage, etc., the cost is based upon the feeding value as compared with that of hay or feed which has a market value.

Pasturage changes were charged on a uniform rate for each route or county. The importance of pasturage in the economy of the farm is well illustrated by the small quantity of grain or roughage fed during the pasture season. For practically five months of the year the cattle were supported almost entirely from the grass crop. During this same period the production was greater than at any other time of the year.

Under farm conditions, with stock of mixed type, milk production is seldom proportionate to food consumption. The general practice of farmers is to make the greatest possible use of roughage and to reduce feeding of grain to a minimum, especially those grains which are of ready market sale. The quantity of grain fed tends to vary somewhat with its price and availability, but there is a decided tendency to use farm grain rather than purchased concentrated mill feeds; this may or may not be good farming. However, if the grains fed are largely those containing high percentages of carbohydrates and fat, and are fed with timothy hay rather than clover, the purchase of concentrated mill feeds become imperative.

Lack of Liberality Greatest Fault.

Theoretically, at least, the greatest error in feeding the dairy cow is lack of liberality. A comparatively small proportion of cows may receive at times a ration sufficient for maximum milk production, but the greater number are constantly underfed. During June, July, August and September, little or no roughage or concentrates are fed. This leaves a period of 243 days during which partial or full feeding has to be resorted to. With an average pasture season of 163 days, there remain 202 days during which a full ration must be provided.

The quantity of milk or butterfat produced per cow affects to a large extent the cost of production per unit of product. Cost of maintenance is approximately the same for a cow producing 5,000 as for one producing 6,000 pounds of milk annually. The only difference is the 1,000 pounds of milk. Therefore, it is economy to produce milk from herds with high yields. Other conditions being the same, a cow with an average of 7,000 pounds per year will produce more cheaply than one with a yield of 4,000 pounds per year, notwithstanding that the latter will show a maintenance cost several dollars less than the former.

Well-Bred Cows Most Economical

Certain tendencies exist in the dairy industry where cows of better breeding, carrying dairy heredity, are being introduced and better shelter and care provided. Under these conditions an increasing percentage of expenditure for shelter, depreciation and interest on investment is natural. Prices remaining the same, the proportionate expenditures for labour and feeds would decrease. Thus, as herds become better bred and of more value a relative decrease in cost of care and of feed may be expected. This is especially true after stock reaches a value of $100 per head.

The expenditures for food, prices being on a stable basis, remain practically the same, even with an increase of productivity of cows and consequently of value. Well-bred herds with an average of 5,000 or more pounds of milk per cow per year, a scompared with herds producing 4,000 pounds per cow, require

(Continued on page 581)

How the Standard Gets Practically All the Cream

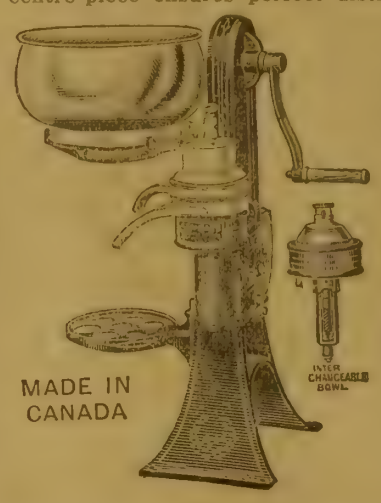
At the point where the good features of other machines leave off is the point where the Standard is just beginning to give you extra close-skimming, extra profit making advantages that open wide the eyes of everyone who cares to make comparisons. The Standard's bowl, the vital part of any separator, is unlike that of any other machine. It gets more butter-fat by far than others, and that is what counts! The

Standard

gets all but one-tenth pound of butter-fat from every 1000 pounds of milk skimmed while other machines lose a whole pound. Compare this record with that of your own or any other machine. And remember that this all-important result is proven over and over again by independent tests made at Government Dairy Schools. Here is the way the Standard out skims other machines:

First—The Standard has greatly improved the disc system. The Standard's discs are different in both size and shape and their advantages were proven by a two year test before being adapted.

Second—The Standard's exclusive curved wing centre-piece ensures perfect distribution and prevents clogging of the discs with cream. See in the picture the wide open space between the tubular shaft and the inside edges of the discs. Half of the skimming is done in that space, thus freeing the discs for perfect skimming.



Do You See Those Wings ?

The curve of the wings increases the distance over which the milk travels and the skimming force is multiplied many times. The curved wings distribute the milk in thin sheets equally to every disc space without clogging. There is no whipping as in the case with straight wings. That is why you can get firmer, better butter when you have the Standard to give you unbroken globules of butter-fat. And you get more of it—more profits—because the Standard outskims all other machines.

Write for booklet describing the Standard's even spaced discs, the easy to clean and easy to turn advantages, the exclusive self-oiling system, the instantaneous clutch, the exclusive interchangeable capacity feature—many special advantages that put the Standard absolutely in a class by itself.

INSTEAD OF PAINT

DON'T paint your pretty home this season, but use instead Velvex Creosote Shingle Stains. By so doing, you can bring out all the beauty of the wood. And think of the preservative value. Velvex Shingle Stains contain Creosote, the greatest wood preservative known. This means prolonged protection against wind and weather. It therefore means *economy.*

Velvex
Creosote Shingle Stains

Half the Cost — Twice the Wear

Velvex Creosote Shingle Stains cost about half as much as paint. And they wear much better because they penetrate the wood. They do not evaporate or dry out and of course they cannot peel off. These stains come in any color you want. They are very easily applied. You ought to investigate them. We have the complete line and we know you will like them.

Write us for a sample of wood stained with Velvex Creosote Shingle Stain.

RASPBERRY BUSHES THAT ARE DISEASED

I have a small raspberry patch, and some of the bushes are dying out. The stalks become dark in color, on some bushes there are caterpillars. The young sprouts are also affected and leaves getting dark and spotted.

J. C.

There are several diseases and injurious insects that attack raspberry bushes, and all of them are very difficult to control. Anthracnose and orange rust are two diseases that affect the leaves and canes, and there is no remedy but digging out and destroying diseased bushes. The insects that do most damage to raspberry bushes are the root borer and the haspberry saw fly. The former can be controlled by good cultivation and destroying weakened plants, and the latter by spraying early in the spring with two pounds of arsenate of lead in forty gallons of water. You should send a sample of the diseased bushes to the botanist at the experimental farm, Ottawa, and he would be able to tell you the disease and remedy. It is difficult to suggest a remedy, without first seeing the affected plants.

SAVE MONEY BY THINNING

We have never been able quite to understand the position of the orchardist who believes that it is a waste of time and money to thin his fruit. It will soon be the thinning season, and the harvest time will show conclusively how mistaken many a grower has been in leaving on his trees all the apples they will bear.

Lately we visited a large, well-kept orchard, where half the crop was undersized and, incidentally, undercolored. It took a lot of those apples to fill a No. 3 barrel. It took the pickers just as long to pick each little apple as to gather the big, blushing beauties. It brought the grower much less per barrel than No. 1 fruit.

The orchardist referred to is a good, careful fruit grower in most respects. He prunes, sprays, fertilizes at the right time—but when it comes to thinning his crowded apples he claims it takes too much time and money. It would seem obvious that if all the apples must be picked eventually, as every one agrees is essential, it would cost rather less, than more, to have them removed while they are small and can be thrown on the ground than when every apple must be carefully placed in the baskets.

By thinning you get fruit of far higher quality, you save your trees from exhaustion, and the actual outlay for thinning is less than if you wait until autumn and have the good, bad and indifferent harvested together.

DON'T KEEP DRONES

We were interested in talking to a man whose theme was that it was unprofitable business taking care of drones in the orchard. The tree that bears little or no fruit receives the same attention and demands the same expense as its fruitful neighbors. It gives no reward for the care lavished upon it.

"What remedy," we asked, "could you suggest for this condition?" "First," he said, "you must catch your drone." His method was to observe his trees individually at harvest time, and, in a notebook, where he kept a page for each orchard row, to write down the aspect and behavior of the tree that answered to a certain number in that row.

In this way he recorded the yield of each tree for a succession of seasons, and, when proof was positive that any tree was not earning its living, he removed it and supplied its place with young, healthy stock. The mere fact that a tree was not doing well did not condemn it. Its symptoms were noted and the best-known remedies given. Generally the tree responded nobly to this attention. If it were suffering from incurable troubles—such as crown gall or hairy root—no time was watsed before cutting it down.

This method of close inspection of each tree was found to be rewarding from many points of view. Poor drainage was detected, bad condition of the soil, frequency and cause of certain defects in the fruit of individual trees. The notebook became a valued business partner. We would like to see our readers enter into such a partnership.

The New McLaughlin Models Eclipse all Previous Standards of Beauty and Value

EVEN more graceful in design with greater power the new series "E" more than maintains the supremacy accorded "Canada's Standard Car" for eight successive seasons.

The famous McLaughlin valve-in-head motor develops more power than any other type of motor of the same bore and stroke, and develops this reserve power with the minimum gasoline consumption. Every mechanical feature of McLaughlin cars has been perfected to the same high standard of efficiency as the motor.

McLaughlin designers and engineers have built 12 body styles of rare beauty—worthy masterpieces of our coach builders' art.

This complete line of 12 new models built in one group of factories and distributed by 12 branches and over 300 dealers from coast to coast includes a car for every need.

PLUM DISEASE CONTROLLED BY CUTTING AND BURNING

In July and August we find numerous interesting abnormalities on the fruit and twigs of the common and wild plums. These abnormalities are manifestations of a disease known as "plum pockets." The name is derived from the way the fruit is acected, it being first discolored, and then rapidly enlarged often to several times the normal. The surface becomes wrinkled, the pit fails to develop, and the fruit consists of only a tough skin. Along with the acected fruits we almost always find distorted and enlarged twigs.. In later stages the twigs are killed and the diseased [illegible] The disease [illegible] H E Vasey, Colorado Agricultural College, Fort Collins, Colo.

DAIRYING.

HOW TO MAKE NO. 1 BUTTER AT THE FARM FROM FEEDING COW TO FINISHED MOULD

Buttermaking is an art, and there are buttermakers and buttermakers. Number 1 butter can be made as cheaply as poor butter, but eternal vigilance is the price one pays. To produce number 1 butter it is very essential that the cows from which the milk is obtained be in good condition. They must not be allowed to eat food that is in any way damaged or anything that is ill-smelling or highly flavored, such as wild garlic and other noxious plants. Nor should they drink unclean water, else they will produce milk from which number 1 butter cannot be made.

Cleanliness from start to finish is of the utmost importance. On our farm we are very particular about keeping the barn and all the surroundings neat and clean at all times. Everything that comes in contact with the milk, cream or butter is kept in as sweet and clean a condition as possible. Before beginning to milk we use a cloth and a brush to clean the udder and flanks of the cows. As soon as the milk is drawn it is strained and separated. We are great friends of the cream separator. We have used one for several years and certainly would not do without it.

As soon as possible after being separated the cream is cooled to 55 degrees, after which it is emptied in with the other cream. Every time fresh cream goes into the cream vessel it is thoroughly stirred into the cream below and the sides of the vessel above the cream wiped clean of adhering cream. This if left, always ripens too soon and mottles the butter.

In making butter we never guess at the temperature of the room in which the cream is kept for ripening or the churning temperature. We use a good dairy thermometer. One can be had cheaply, and will return its cost in a short time. In ripening the cream we bring the temperature up to 70 degrees by placing it in a warmer room, with the thermometer hanging by the cream cans. After the cream is ripened, which takes about 12 hours after bringing it to a temperature of 70 degrees, we cool it down to 62 degrees by placing it in a cool room, then hold the cream three hours and a half before churning.

It is very essential in cream ripening to stir the cream frequently to insure uniform ripening. When cream remains undisturbed for some time the fat rises in the same way that it does in the milk. Instead of being smooth and glossy it will appear coarse and curdy when poured from a dipper. As a rule ripening gives better results than slow; for instance, when cream is ripened at a low temperature more or less of a bitter flavor is the result, and if kept too long after ripening to churn it will have an off flavor.

Before putting the cream in the churn we scald the churn thoroughly with hot water, then rinse with cold water. This freshens the churn and fills the pores of the wood with water, so that the cream and butter will not stick. We think the churn has a great deal to do with the appearance of the butter. We use an ordinary barrel churn because it churns easily and quickly and there is no dasher inside to beat and break the grain and make the butter look like lard with butter color in it. We use butter color in winter, but never in summer. We carefully strain all the cream into the churn. This removes the possibility of white specks in the butter. The churn is never filled more than half full of cream.

We churn all the butter until the granules are about the size of grains of wheat. When the granules are larger than this it is more difficult to remove the buttermilk and distribute the salt. As soon as the butter granules are of the size mentioned we draw off the buttermilk and put in as much water, which is at the same temperature as the buttermilk or a degree or two warmer, as we have buttermilk. We then revolve the churn three or four times, draw the water off, and have a pail of clean cold water, which we pour on the butter until the water runs off clear.

Too much emphasis cannot be laid on the quality of the water used in making butter. It should be absolutely free from all vegetable or mossy taste or odor. Minerals must not be in excess save salt and lime and these two not to any great degree. We use clear spring water that seems to be just exactly right for use in making good butter. It is not necessary to say that none other than the best grade of salt should be used in salting butter. We prefer the flake salt, as it dissolves more readily and is not so liable to make mottles as other kinds of salt. The amount of salt to use in butter is a matter of taste and opinion. Salt adds flavor to the butter and materially increases its keeping qualities. Very high salting, however, has a tendency to detract from the fine, delicate aroma of butter, while at the same time it tends to cover up slight defects in flavor. As a rule we salt our butter rather highly. Salt very readily absorbs odors, and must therefore be kept in a clean, dry place where the air is pure, and should be at the same temperature as the butter when used.

The chief object in working butter is to evenly incorporate the salt. Our method is as follows: After the wash water is drained off salt is carefully distributed over the butter then the churn is worked just enough to get the salt into the butter, after which the butter is covered and let stand for 20 minutes or a half-hour to allow the salt to dissolve. The butter is then removed to the butter worker and the process of working is finished by working the butter enough to get the salt evenly distributed throughout the mass.

After the butter is worked it is molded. We use one-pound brick moulds. Each cake is wrapped separately in parchment paper bearing our farm name and address in fancy letters, and the butter is ready for market. We never ship our butter to distant markets. Our entire output is sold to a reliable grocery dealer in a nearby town and we always receive more for the butter than is paid for butter by City Commission men. We could sell several times as much butter if we could supply it. M. E. U.

SALTING BUTTER IMPORTANT TASK

While it may be pardonable to estimate the weight of butter in churning which some are able to do with surprising accuracy, it is never a good plan to "guess" at its weight of the salt required for churning. On each and every dairy farm where butter is made there should be a scale that will weigh to ounces or finer, and both the butter and salt carefully weighed before the latter is added to the former.

FIVE great oil refineries from British Columbia to Nova Scotia—five principal factors in the country-wide organization which has made possible the supplying of high grade oils to every Canadian farm at a lower price.

We know Canada. We know farming conditions East and West. We know the lubrication requirements of the machines you use on your farm.

All our oils are supplied in steel barrels and steel half-barrels—convenient, economical. No waste. You use every drop you pay for.

Wear PALMER-McLELLAN'S Chromoil Tanned Farm Boot

THIS SUMMER

POST PAID TO YOU

$4.50

"The Boot with the Moccasin Comfort"

Here at last is the perfect combination of boot and moccasin. The general shape is that of a moccasin, but the boot is built on a last, with a long solid counter to hold up the heel. It has all the easy foot fitting comfort of a moccasin, and, at the same time, it will stand right up and keep its shape with any boot.

The new chromoil leather used is simply wonderful. The chromoil tanning process produces a through-and-through, instead of a surface, waterproof, and a leather much stronger and more durable than any other. These new farm boots will not crack and shrivel when dried by the fire. They remain pliable in weather that freezes other oil-tans. They outwear any other boot of their kind on the market, and give solid comfort and satisfaction every day.

If you have any trouble getting these new Palmer-McLellan Chromoil Tanned Farm boots locally, mail us the price and we will ship you a pair postpaid.

Men's Sizes 9 inches high, per pair $4.50

ADDRESS DEPT. M

Palmer-McLellan Shoepack Co., Limited,
FREDERICTON, N. B.

Write for free booklet describing Chromoil Tanned Leather and its merits.

The amount of salt to add to butter varies, first, according to the requirements of the market and secondly, according to the methods of making butter. No butter should contain over about 3 per cent. of salt. This is about the maximum that can be properly dissolved in butter. Butter cannot contain more than 16 per cent. of the moisture and inasmuch as water is the only dissolving substance in butter it can readily be seen that the amount of salt that will dissolve in butter is limited. If we wanted butter to contain 3 per cent. of salt and all of the salt added would be retained by the butter then we would add two and a half pounds of salt to each 50 pounds of butter which would be about three-fourths of an ounce to each pound of butter.

Ordinarily some of the salt added to butter is lost. Usually the salt is added to the butter before the water is all worked out. Some of the salt will go into the solution and drain from the butter in the form of brine. This is especially true when the butter is made in large quantities. When it is made in small quantities very little of the salt will be lost in this manner.

From 2 to 3 per cent. of salt will suit most customers, so in making butter on the farm from 1-half to three-fourths of an ounce of salt per pound of butter is as nearly right as can be. Care should be taken to use salt that is flaky. Salt that has stood in a damp place and become hard should not be used as such salt dissolves with difficulty. Salt takes up odors very rapidly and for this reason it ought to be kept in a clean place where there is no undesirable odor of any kind.

The butter should be taken from the churn in the granular form, weighed and placed on the worker, after which the salt should be weighed and added to it. The salt can be more evenly distributed when the butter is in granular form than when it has gathered and even distribution of the salt throughout the butter is of course a very important feature in first-class butter production. The butter should be worked until all the salt is dissolved, otherwise the butter will be gritty and gritty butter is not desired by anyone. C. H.

MKAING ICE CREAM; A STANDARD RECIPE

In making ice cream the following hints should be borne in mind: The best cream to use is double cream; the next best single cream. By way of explanation. Cream which is skimmed off of milk after it has stood 12 hours is called single cream; that which is taken off at the end of 24 hours is called double cream, and that taken off at the end of 36 hours is called butter cream. The best double cream and which can all be whipped to a stiff froth, is obtained by letting single cream stand 12 hours, and then taking off the richer part. If any milk is used it is apt to give the ice cream a mushy, snowy taste, because the water it contains will freeze into coarse crystals, and it melts quicker than when pure cream is used. However, very good results are obtained by using some milk. When short of cream, it is well to remember that to add a little, if not more than half a teacup, is always better than to use none.

Double refined or sifted white sugar is the best to use.

The best ice to use is snowy ice which is full of air holes, and is readily penetrated by the salt. The ice is most easily broken up by putting it in a coarse bag and pounding it with an axe or mallet until broken in pieces about as large as walnuts. The finer it is broken, the faster it melts. Pack it firmly into the freezer, add enough water to make it into a thick mush, and then put in the salt (the coarser the salt the better.)

It is not necessary to draw off the water as fast as the ice melts, but wait until it floats the ice.

Before beginning to freeze ice cream, let it stand in the freezing can, packed with ice, but covered only with gauze, until it is thoroughly chilled; if this is done it will freeze more readily and take less ice, and also, if not cooked, it is apt to become granular, or curdle, if the attempt is made to freeze it while warm or lukewarm; in any event it should be thoroughly chilled before freezing.

Newly frozen ice cream is apt to be mushy, and lacks flavor and consistence, so that after being frozen it is best to pack it down and let it ripen 4 or 5 hours before it is served. In packing down ice cream which is to be kept for some kind, turn off the brine, pack in some coarser ice and salt, and cover with an old carpet or piece of blanket wet in brine.

It is best to do the freezing in a warm room, because the ice melts more rapidly, but after it is frozen, however, the cream must be kept in a cool place.

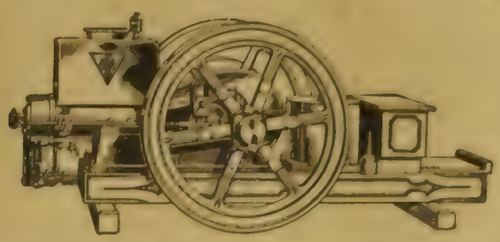
Once freezing operations have begun, continual stirring is necessary, and any cream which washes up against the side of the can and freezes must be scraped off and mixed in with the balance of the contents. Unless the contents are thoroughly stirred before the freezing takes place the whole will be spoiled. The dasher of the freezing machine must not be turned rapidly, as that prevents the cream from being smooth. Turn evenly and moderately quick.

The first step in the making of ice cream should be the packing of the freezer, so that the ice and salt may get thoroughly chilled. Use one part salt to three parts ice.

Standard Recipe

One quart cream; 1 egg; 1 cup sugar; 2 to 3 teaspoons flavoring, according to strength. Add yolk of eggs and sugar together and beat. Then add this to the cream. Put in the freezer and when partly frozen add the beaten white of eggs and just before finishing freezing add the flavoring.

ALPHA



—the engine that takes the work out of farmwork

An Alpha will saw more wood in a day than you can saw by hand in a week.

It will pump water all day long without watching.

It will run your separator, churn or washing machine.

It will run a thresher, feed cutter, or silo filler.

There will not be a day when you cannot find some way in which your Alpha will save time, money and labor for you.

Owning an Alpha is cheaper than hiring someone else's engine. The money you now have to pay out for engine hire when you need power, and the greater amount of work you could do if you had an engine of your own would soon pay the cost of an Alpha

The Alpha is a simple, powerful engine that will give you more reliable service and cause you less trouble than any other engine you can buy.

Ask for catalogue, prices and complete information. Made in eleven sizes, 2 to 28 H. P. Each furnished in stationary, semi-portable or portable style, and with hopper or tank cooled cylinder.

GROW THE HOG THAT PAYS PROFIT ON FEEDS AND SATISFIES THE PACKERS

It is a fact that the potential superiority of the pure-bred hog has become so thoroughly established in the breed that when mated with females of no breed, reasonably satisfactory results are secured. It is often the case that the grade dam will give birth to satisfactory large litters, a matter in which she is probably the controlling factor, but the qualities of quick growth, uniformity, early maturity and sometimes the profitable outcome of the litter are generally due to the prepotent, transmissible superiority of the male. If this were not true then all our boasted progress in animal husbandry is a delusion, and all our care and expense of keeping strains, families and breeds pure, making pedigree records, and selecting for type and performance are wasted efforts of enthusiasts.

If it is true that there is merit in purity of blood, which has been intelligently selected and concentrated, then it is absurd and disorganizing to advise that the most profit lies in the cross-bred practice of diffusion. Indeed the opinion may well be entertained in all our lines of animal husbandry that diffusion is much too general by the unwise, violent outcrosses within the breeds.

The fundamental object in swine breeding is for the production of the greatest numbers of quickly growing pigs. Hog raising is purely a market proposition. A man may keep a horse or a cow—even a dog—beyond its years of real usefulness for love or association's sake, but with the hog our regard for him is purely mercenary.

We have, therefore, come to regard prolificacy in the swine mother as of very great importance, so much so, indeed, that we do not always differentiate between numbers and profit, for all experienced hog raisers know that it is easily possible for an over-zealous sow to numerically discount herself by producing a larger number of pigs than she can raise well.

As a rule, for the average sow it will be found that there is more ultimate profit in a litter of ten pigs than in one of twelve, and often more in eight than in ten. The successful orchardist thins his fruit to the ability of his tree, and I am sure all growers of pigs may at least consider this as a suggestion to them. But the number of offspring recommends the sow to most owners and therein may rest the popular but absurd idea of mixing pure blood with plebeian in swine.

The best type of hog from the standpoint of the packer is the one that will cut out on the block the most valuable meat with the smallest per cent. of cheap meat and offal. The ideal hog from a packer's standpoint, as I see him, beginning at the front end, should have a medium short head with a medium to small ear, jowl full but not heavy and baggy, as it furnishes cheap meat. The neck should be short and full; shoulders set well in line with the sides and rest of the body with no tendency to shields or thick hide. The chest should be full and well let down with good width between the front legs, and there should be no depression back of the shoulders, either on top or at the sides. The lower line of the chest should make a perfectly straight line with the lower line of the belly and flank.

The back should be slightly arched with rib well sprung, but not beyond the side line. A stick standing perpendicular and touching the edge of the rib should also touch the belly line and side at every point. The loin must be thick and full and the mat covering the loin and the back should be of firm quality, but not hard. The sides should be perfectly straight and deep with the flank low and in line of the belly. In my opinion, no point is more overlooked and is less considered by hog breeders than the flank. A deep side and middling cannot be had without a low, deep flank, and a good flank is very seldom seen without a correspondingly good side and ham.

The two points most indicative of a quiet disposition, easy feeding, early-maturing hog are head and flank. The rump should be almost level with long coupling and tail well set up in line of the back. A short coupling is nearly always accompanied by around rib, high flank and not enough body depth. The ham should be even with the rib and side line and let down well to the flank, but not out of line or proportion with the rest of the body. A big, bulging ham is very seldom seen on a well proportioned hog, whose top and side lines are even and where the flank is properly let down. A very wide ham goes with a high flank and round rib, which generally means not enough depth and width below. A baggy ham at the bottom, often termed by breeders a "meal sack" ham, is undesirable to the packer, all the lower, flabby meat being waste.

Good length is desired. The distance from the root of the tail to the centre of the forehead should be about the same as the flank and heart measurement. The legs should be set well out at the corners of the body, and be straight, tapering nicely to the foot, with short pastern joint and toes set closely together. The bone can be heavy, if short, although a medium bone of good quality, sufficient to carry a heavy body, suits the packer just as well. A big, coarse bone and long legs very seldom have the uniformity and quality to bring a top price.

The coat should be smooth and soft to the touch, which usually indicates a thin hide and good quality of meat. Probably the most important point of all is the body surface, which should be perfectly smooth and free from wrinkles and creases. The flesh should be firm to the touch, soft, blubbery flesh that puts on unevenly being almost as undesirable as a thick, wrinkled hide. Evenness and smoothness are things most desired by the packer.

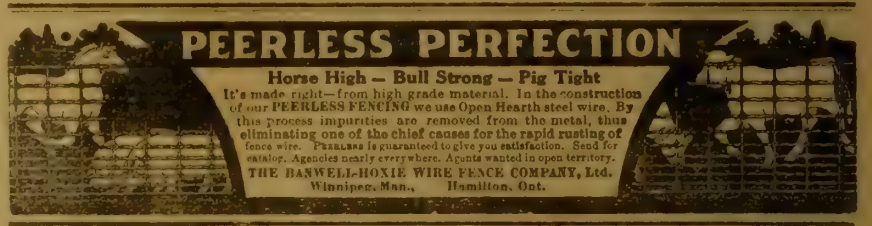
CALVES WITH SCOURS ARE NOT THRIVING

I have a number of calves out on grass betting a little separated milk. They have the scours bad for a month. I have tried everything but cannot get them stopped. The calves are very thin. Kindly advise what would be good to stop the trouble. H. J.

In suggesting a remedy for the difficulty we would be in a better position to do so had our correspondent told us the age of the calves, their treatment before going on to grass, how long they were fed whole milk, manner of making the change, the age that they began to scour, the quantity of skim milk fed, etc.

Scours in calves are almost invariably (unless a germ disease brought on by improper feeding and once they become chronic are often difficult to cure.

In the first place the new-born calf should be fed its mother's milk for a few days, either by allowing it to suck or by feeding it from a pail. If the former, it should not be allowed to gorge itself or this may bring on scours at once. It must be remembered that domestic cattle are not under



PEERLESS PERFECTION
Horse High — Bull Strong — Pig Tight
It's made right—from high grade material. In the construction of our PEERLESS FENCING we use Open Hearth steel wire. By this process impurities are removed from the metal, thus eliminating one of the chief causes for the rapid rusting of fence wire. PEERLESS is guaranteed to give you satisfaction. Send for catalog. Agencies nearly everywhere. Agents wanted in open territory.

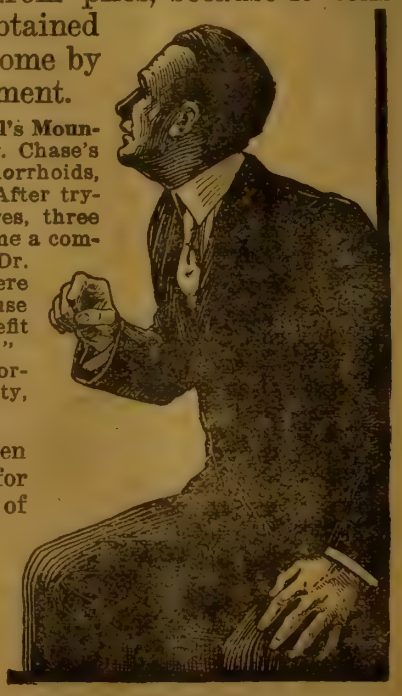
Piles Cured
By Dr. Chase's Ointment

IT is a surprise to many to learn that there is any cure for piles short of a surgical operation. The doctors have encouraged this idea until the sufferer from this annoying ailment lives in constant dread of the surgeon's knife.

This letter from Mr. Campbell carries a message of good cheer to all sufferers from piles, because it tells how relief and cure can be obtained in the quiet of your own home by the use of Dr. Chase's Ointment.



Mr. Donald M. Campbell, Campbell's Mountain, N.S., writes: "I have used Dr. Chase's Ointment with great success for hemorrhoids, or piles, of fifteen years' standing. After trying all kinds of so-called pile cures, three boxes of Dr. Chase's Ointment gave me a complete cure. I have also used Dr. Chase's Kidney-Liver Pills, and there are no others so good. You may use this letter, if you wish, for the benefit of others who may suffer as I did."

(Sworn before me, Murdoch Gordon Campbell, J.P., in the County, and for Inverness County.)

You are not experimenting when you use Dr. Chase's Ointment, for it has an unparalleled record of cures to back it up. Beware of imitations and treatments said to be "just as good." They only disappoint. 60c a box, all dealers, or Edmanson, Bates & Co., Ltd., Toronto.

natural conditions altogether and give much more milk, hence the danger of calves taking too much feed right at the start. If the calf is fed from a pail it should be clean (any old pail isn't fit to feed a calf from) and the milk should be warm. If it has cooled off perceptibly the pail should be set in another larger one into which a quantity of hot water has been placed and restored to the original temperature. From one or two quarts three times a day will be sufficient for the first day or two, gradually increasing to a full feed, being careful at all times not to give too much or there will be trouble with indigestion and scours. No definite amount can be stated as the proper quantity to give a calf. Two quarts may be too much for one calf, while on or even two gallons will not be too much for another as it grows older.

Where calves are to be fed skim-milk the change may begin at about three weeks old; possibly sooner, but it pays to give a calf a good start and nothing will do it as well as the warm whole milk. The change should be very gradual substituting an equal quantity of skim milk to the amount of whole milk withheld until at the end of a week or two days a complete change has been made. At the same time a teaspoonful of boiled flax seed made into a jelly should be added to the feed and increased accordingly, until half a cupful is reached twice a day to two months old. At one month old the calf may be given a handful of corn meal and wheat bran in equal parts increasing with its age. If desired the flax seed jelly may be gradually dispensed with as the corn and bran increases. The latter should be fed dry in a clear box or pail with a pinch of salt daily and all the clean fresh water and sweet fresh clover or alfalfa either green or dry, it will consume.

Many calf feeders are careless about the condition of feeding pails and allow them to become dirty and sour, which is pretty sure to induce scours or indigestion sooner or later. They should be kept clean even if it is necessary to scald them occasionally for this purpose. The same may be said of the manger, watering troughs and pens. No calf will thrive on dirty feed and in filthy quarters.

Too much attention cannot be given the matter of regularity in feeding milk and having the temperature right for young calves. Cold milk, and particularly cold skim milk, will almost surely bring on scours.

Giving so much attention and care to the young calf may seem fussy and unnecessary to some, and there are, no doubt, individuals which are not so readily affected to adverse conditions as others; but at the same time, it is the experience of most feeders that sooner or later neglect to observe the laws of nature and sanitary conditions will bring them into trouble. "An ounce of prevention is worth a pound of cure," and in the end is usually much easier applied and immensely more profitable; for it is only as calves are kept in good health and growing rapidly that the best results can be obtained from any economical standpoint.

For your calves we would recommend a dose of castor oil to clear out any irritating matter from the bowels and the feeding of whole clean milk for a few days until the normal state has been reached, and then a gradual change to the skim milk as suggested above.

The EMPIRE'S NEED

is YOUR OPPORTUNITY for Splendid Service and Substantial Returns

The seriousness of the food shortage is clearly shown by official figures as well as by prevailing prices. The world's crop this year can scarcely be sufficient for twelve months, so that the need in 1918 will be still greater.

This shortage not only threatens hunger for most of the civilized world, but it threatens the victory of the Entente Allies. The extra supplies so urgently needed must come chiefly from the farms of Canada and the United States—for the other great wheat producing countries are so far from Europe that the scarcity of ships prevents full utilization of their crops.

On every Canadian with land to till this situation lays a tremendous responsibility. At the same time it opens up a wonderful opportunity to transform daily work into the highest patriotism and National Service—to feed the men and women who are fighting and working for victory--and to secure such returns as have seldom been known from farming.

These exceptional returns present another chance to serve the country to—

BLOODY MILK, ITS CAUSE AND CURE

What shall I do for a young milch cow that gives bloody milk from one teat. Have given her one pound salts every other day for ten days, and she is not improved. J. B.

Bloody milk may occur shortly after calving because of a partial breaking down of some of the secrteing cells of the udder. Bloody milk may also be due to an injury to the udder such as striking it with the hocks. The latter condition might take place quite frequently during flytime when the cow is fighting flies. A cow with a large, rather pendulous udder will be more likely to injure the udder during this period. Another cause of bloody milk is the presence in the udder of lesions of tuberculosis. In this case there can usually be detected some hard, firm lumps in the udder. In treating or doing away with the trouble, the udder should be bathed with hot water twice a day. Milking out the udder three or four times a day will further encourage a termination of the trouble. If the pasture is some distance from the house it would be a very good plan to milk the cow in the pasture instead of bringing her all the way to the barn with a distended udder. Unless the bloody milk is due to tubercular lesions you can expect by proper handling to be rid of the trouble in a reasonable length of time.

THE HORSE

THE HORSE AND THE SYMPATHETIC HAND

A man came to my place the other day for whom I have rebitted several horses. He asked me to drive around and examine his road horse's mouth. I consented on condition that he would do my job of sprinkling the grass, in my absence. It was exceedingly dry and I have arrived at an age where a grass-patch is one of my chief anxieties. The horse went all right, but when I got back that man was fighting the hose. "Here," said he, "take it. I never saw such a thing; it has nearly twisted my wrist off." It was a revelation to me that the man would fight anything, even a hose. Instead of letting it turn its twist out he had fought and held it for the half hour I had been absent. Of course that is the way in which he handles a horse's mouth.

Now here is an opposite case. A woman who has a big stable of show horses became seriously ill and her doctor forbade her to resume driving any horses that pulled. Her manager rebitted the whole stable, getting them light on the bit, and she drove them that way with more success than before. Their action was lighter, airier, yet truer than when they were lugging.

Hands, that is all. The sensitive hand which can give and take, which should be normal on the snaffle, is far more difficult to acquire with heavy bitting, which makes horses more or less uncomfortable and leads them to est themselves against one. The worse the hands, more inadmissible is heavy bitting, especially since few understand the adjustment of curbs, parts, gags and other contrivances, yet we see poor express horses and slaves that need no restraint, hampered with such contrivances to make their lot yet harder, and ignorant drivers jerking their mouths to stimulate their efforts.

The city horseman is almost a man of the past. There need be little regret, if our good friend horse passes altogether from the cruel paved surfaces, ill-ventilated stables and the hands of the cruel and ignorant, and begins and ends his career upon the farm, where as a rule, he meets with some consideration and is among friends, where the end of his life is made easier instead of increased in hardship, as he is less able to bear it.

Farmers will lose a osurce of profit if they cannot sell the big ones to the city, but the country will reap the benefit of horses at the height of their powers, trained to farm work, so that they will be a more efficient part of the farm equipment.

THE EFFICIENT HORSE IF PROPERLY HANDLED GIVES HIS LABOR FREE

In these days of commendable anxiety to increase the output of Canadian farms it is well worth while for us to remember that after all has been said and done about supplying mechanical power to do field work a large amount of the farm work will continue to be done by horses. There is much that the tractor can and should do, but the statement lately appearing in a literary weekly to the effect that the farm horse's days are numbered does not seem to be justified unless a large number is used. Some farms may dispense with the horse, but many more will continue to make a large use of it for doing all kinds of field work. The efficient horse will find worth-while work to do for a longer time than will the horse that for one reason or another is poorly qualified for exacting work.

The difference between the results that are secured from a day's work with a team that is strong and active and from a day of partial loafing on account of ineffective horse power amounts to a great deal in these days of urgent need for doing the maximum amount of field work. A number of striking examples of slow farming due to inefficient horse power may be found in almost any community, especially where small farms are the rule. The handicap imposed by delayed spring work is one that can hardly be overcome, no matter what is done, for the season's work needs to be turned off on time if the "Food Production" programme is to be carried out.

The horseman with a true interest in his team must remember that the succulent feed of summertime has a softening influence on the staying power of the animals. This comes at a season when their staying powers are most required, and accordingly it calls for some intelligent consideration. In nature, summertime is the animal's easy time, in the domestication of the horse it is his hard time. Yet it is possible, when rainy spells come with idle days on the grass, to do much to prevent the softening that is too often allowed to occur if field work is interfered with by bad weather or any other hindrance. It is detrimental to the health and spirit of the team to work them full steam ahead when newly taken from two or three days' freedom off the grass field. It

Costs No More Than a "Span"—

It seems almost impossible, but it is true that you can get a handsome, comfortable, speedy 5-passenger Ford motor car for no more than it would cost you for a span of good driving horses, a carriage and harness.

The initial cost of a Ford car is so small that every progressive farmer can readily purchase one.

And who wouldn't rather motor to town, to church, to the railway station, to the neighbor's, than drive? — especially when it is three times as fast to motor, more comfortable and less expensive.

The low cost of running the Ford makes motoring possible for the masses, where it was formerly a rich man's luxury. It makes motoring a matter of good business, especially for those whose time is valuable. And with labor so scarce no one needs the time-saving Ford so much as the busy farmer!

is better to take them in over night before the day intended to work them, and treat them to a grain feed in the morning and a little hay.

If it is not possible to find work that may be done when fields are not fit to work in the horse may usually be given exercise by turning him into a paddock or field, remembering that it is not wise to take away all of the grain feed, but rather that it is advisable to feed enough grain to keep the horse in strong condition.

Veterinarians tell us that there is a great danger of serious illness due to azoturia if care is not exercised when the work horse is kept in the stable for a few days following a period of active work and generous feeding. The way to avoid this serious disease is to see to it that the horse takes some exercise every day if at all practicable, or to reduce rather sharply the allowance of grain feed when enforced idleness is experienced. The losses from this disease constitute a considerable part of the avoidable waste in livestock management, and it is important that all of this waste be eliminated at the earliest possible moment.

There are many horses that are fed so small an amount of grain, even while at hard work, that they are physically unfit to do a really good day's work. The use of a fair amount of feed for the work horse is necessary if he is to perform his work in an acceptable way, and the economy that is attempted through cutting down the grain ration of the hard-worked horse is not true economy.

When all grain feeds are as costly as at present it is not possible to formulate a ration that will be cheap and efficient. In general the work horse that is used for fairly hard work should receive approximately a pound of grain and a pound of hay daily for each hundred pounds of his weight. The proportion of grain to roughage depends on the amount and kind of work to be performed. A horse hard at work should never be expected to consume more roughage than grain by weight, that is in his working hours. Oats lead easily among the grains as a horse feed. When it is fed, the horse exhibits mettle as from no other food.

Although there is some complaint on account of the fact that horses are selling at prices which are not in keeping with the prices for which other farm animals sell at present, yet it cannot be said that good horses are low in price, and there is no apparent reason why all good mares should not be bred this season. Increased farm production, the resumption of normal shipping of export goods, as well as the great need that will exist in foreign countries for horses after the war, all unite to make the future of the horse business seem likely to prove profitable to the man who is careful to produce only efficient animals.

The brood mare which works and raises a colt is an efficient farm animal and deserves a place on far more farms than are now giving her a place. If a really good mare is owned it is well owrth while to see to it that she is bred to none but a good stallion. If colts are being raised from mares that are being worked both the mare and the colt should be generously fed. The underfed mare that is working and producing milk at the same time is really being mistreated. A good feed of grain each day for the colt will do much to hasten the date at which he may be weaned, and will also save the mare, for the well-fed colt will not suckle the mare as hard as will the colt that has but little food other than that furnished by the mare. This does not mean that either the mare or her faol needs be pampered, but rather that there is real need of supplying a generous amount of suitable feeds if the mare and colt are to go through the summer in good condition. It is better to keep the colt in the barn while the mare is at work, instead of allowing it to follow the team in the field, to the detriment of both the mare and the colt.

The comfort of all horses that are at hard work should be given careful attention, if best results are to be secured. The horse that has an ill-fitting harness to gall and bruise him and a stall that is uncomfortable instead of affording ample room, a clean bed, and adequate ventilation and light, should not be expected to come up to the high requirements that are set for the efficient horse this year. The genuine horseman will not find it burdensome to do things for the comfort of his horse that many would think of little consequence, and it may be that no one of these things is of much importance, but in the aggregate they surely amount to a very great deal, often meaning the difference between keeping a team at work and being kept from the field on account of the avoidable bad condition of one or more of the horses.

If the high mark that has been set for Canadian crop production is reached this year it will be in part because there has been available a generous supply of horse power with which to till and harvest the abundant crops that are so sorely needed by a war-torn and hungry world. If the horses efficiency is impaired by poor feeding, uncomfortable quarters, inadequate care, poorly-fitting harness, or lack of water during hot weather (especially after the evening feed and as needed during half-days), the teamster may with perfect propriety be charged with neglect of man's best wartime animal friend—the efficient horse. B. E. CARMICHAEL.

POULTRY.

MAKE HENS PAY THEIR WAY EVERY MONTH IN YEAR

We have modified native habits and characteristics of poultry by combining systems until, like all domestic animals, they are the product of their surroundings. Any method of feed, care and housing will ultimately tend to develop a type adapted to the special conditions created. Just as we try to adapt conditions to circumstances, Nature attempts persistently to adapt stock to its environment.

This is why concentration on any one system designed towards certain ends will finally succeed. Success can be attained by any harmless correlation of breeding, selection, feed and care; and permanent success can not be secured by any but persistent consistent methods.

If we select breeding stock, year after year, with clearly defined unchangeable objects, cull and care for flock with these ends in view, we will win success. And if, at any time, we shift to an entirely different method .even if that new method be equally good or even more scientific) we will need to adapt our stock to the change, and for a long time get uneven results.

Why?

Becouse Nature will have been working with the first long-continued combination, and has therefore aided a given strain of fowls, in a given locality, with the given methods of a given person to bring forth results. To change any phase of this combination is to give Nature a new problem, and the worthy dame has never been quick to revolutionize her processes as she is naturally conservative.

We do not yet understand the mysterious mechanism of a hen. We do not even know why she manufactures quilled plumage and shelled eggs from material from which other animals get unlike results. We do not know why the hen's organs manufacture specific ferments which enable her to digest and assimilate rock and mineral substances. We simply recognize these facts as part of Nature's ways, and accept them.

We do know that fowls eat a wonderful variety of plant and animal feed when they can get it, and that a large rich range furnishes the foraging birds with food-elements which they seem to require. We also know that our flocks should have inherited tendencies of hardiness, resistance, immunity to disease, and ability to get the best possible results out of the elements obtained from air, feed and drink. We also know that the degree to which a hen may develop its various functions depends upon the inherited tendency and that any predisposition in any direction is determined by the keeper's ability to breed good or bad characteristics in or out by proper methods. Just what special things contribute most toward certain desirable or undesirable results are not altogether known.

As an egg is largely water, it is self-evident that a hen must obtain a great deal of fluid either i ndrink, mash, fruits or vegetables. And it is certain that all other elements in the egg must be supplied the hen, for she is not a fakir.

There are three kinsd of nutriment which nature supplies in food; proteid or nitrogenous material; fats; and starches and sugar, which are called carbohydrates. Nitrogen, sugar and starch are terms easily understood, so they are preferable to such words as protein and carbohydrate. Starch and sugar become identical when digested and are the chief source of fat, the nitrogen may also be turned into fat.

Fat in feed is not necessarily turned into bodily fat. The individual hen which has the constitutionel tendency to use fats for burdensome flesh, instead of converting it into energy, simply has that idiosyncrasy. She does not long belong in the breeding pen. he is usually a lazy bird, which is why she is filled up with layers of free fat. Though such a condition may be induced by too liberal supply of sugar and starch in the feed, the hen which is so affected is of little value in the laying pen. Such a hen is a nuisance, because the care and ration suitable for her would not be proper for the birds which really are valuable for egg-production. Her elimination from the flock is an important but much-neglected law of breeding. The right kind of birds will never suffer from liberal feeding, if given opportunity for exercise. Birds who thus misappropriate feed are only fit for table use nad should not run with general stock. Culling and careful breeding will prevent the effort sometime wasted in preventing fowls from becoming too fat.

Dry feed and fresh-air houses are advances toward nature's methods. Those of us who have tried them are satisfied with results; but for many, they mean a radical change in surroundings of flocks and should be adopted gradually, else will nature rebel at the sudden change. All efficient labor is applied science, and these two methods are scientific and natural; but the most scientific of us should move slowly with things we do not fully understand.

Even with the best of care, none of us will elevate the entire flock in one or two generations. Nature will reward any correct move by a few superior specimens; but this is only because she will perpetuate the individuals best fitted to environments, for what we regard as successful ways are not Nature's original ideal as to result. Nature never intended any bird to lay enough eggs to satisfy present-day keepers, who of course wish the poultry to revert somewhat to the ways of fish in prolificacy. What we call the best specimens are therefore not what Nature considers best. They are those which have responded to all that made for our own ideal in the method of selection, feed and care. When we strike the right combination, we must—so far as possible, personally apply the combination of factors which have produced them. Any departure from the natural, or any desired improvement, may be fixed in the strain only by careful selection of breeders followed by a system of feed and care which is appropriate. We may consider any superior specimen which appears in our flocks a proof that nature is working in harmony with our method, and that each generation will be better fitted for that method if we continue to use it properly without any extreme changes in our modes of maintenance and care.

These things are the basis of the flock which averages a two-dollar profit for each bird. To make that profit on any hen with only an average lot of birds necessitates the keeper hatching enough chicks so that he can cull very closely, get rid of all superfluous birds, and keep no old birds except for breeding purposes. By December, every chick hatched this spring should have paid for its feed eight times over—even if all feed is bought —and they should continue to be profit-makers on a big scale until April.

If there is a month in the year in which the flock does not pay full value for all the feed consumed, the keeper's method and nature's ways are antagonistic. As nature cannot be coerced into making quick, radical changes, this means that the keeper must readjust his own plan of action.

LILY WHITE CORN SYRUP for Preserving

Use one-third "Lily White", and two-thirds sugar by weight. This prevents Jellies from candying and protects preserves of all kinds against fermentation and mould.

THE CANADA STARCH CO. LIMITED,
19 MONTREAL.

AN OINTMENT FOR VERMIN ON CHICKS

Don't forget to dose the hens and chicks, after feathering, with an ointment made of equal parts of blue ointment and vaseline or lard carefully mixed together. Rub this ointment thoroughly onto the skin under each wing and also a little below the vent of each bird, using a portion of the ointment the size of a small grain of wheat for each of the three places, and half as much for a half-grown chick. Repeat once in two or three months. This is a sure remedy for all kinds of external poultry parasites except mites.

For mites keep the roosts and nests painted once a month with coal oil or, better yet, crude petroleum. Also paint with the same preparation the coops where the young chicks sleep.

POULTRY NOTES

It is a good plan to have awnings or hoods of cheap muslin or boards to go over the windows of the hen house to keep out the sun, and thus keep the house much cooler. But it is not advisable to have these awnings up during the winter, as the sunlight is needed in the houses to purify them.

WHY DREAD OLD AGE?

IT should be the pleasantest time of life and if coupled with good health it is. Many of our most remarkable men and women have won fame and prominence after reaching the sixties, and in lots of cases they have not been robust in youth.

The secret of health in old age is the prevention of bowel disorder. Constipation is the foe to be dreaded. Care in diet is necessary, also the avoidance of harsh cathartics, which only aggravate the trouble.

The ideal laxative for aged people is Chamberlain's Tablets

On account of their mild and gentle action, you hardly realize that a medicine has been taken. Yet the effect is none the less certain, and the tonic properties of these Tablets so build up and strengthen the digestive system that the health is greatly benefitted. Try a bottle today.

HOW TO TREAT FARM POULTRY WHILE MOULTING

One of the most trying times for the poultry will soon be at hand, and this is the moulting period. It is most essential that the fowls have the best of care at this time.

The fowls should be kept as cool and comfortable as possible. Heat has a debilitating and weakening influence on the birds and renders them in a physical condition so low as to make them unfit to cope with the trying ordeal they must undergo while moulting. The fowls should not only be kept cool in the daytime but at night as well. To permit them to become overcrowded and overheated at night will do nearly as much harm as confining them in bare yards in the sun. The roosting quarters should be kept as cool and free from vermin as possible. The roosts and supports should be sprayed often with coal oil to get rid of mites. Ample roosting quarters should be provided so the fowls won't need to crowd and become overheated. If there are no trees to shelter the windows from the rays of the sun, then some means should be adopted to exclude the sunshine. A sort of awning constructed on the outside upper half of the window will tend to keep out the sun and at the same time permit the cool breezes to enter. By excluding the sun entirely during the day the coop will be much cooler during the night. Were the sun permitted to shine in the windows the interior of the poultry house would become heated up very quickly and would be cooled off with difficulty.

Those who raise exhibition birds appreciate the fact that shade is very essential. Mottled or twisted feathers often develop during the moulting period and they can often be attributed to the hot rays of the sun. Unless the defective feathers are detected in time to be corrected the winning chances of the birds are often destroyed. When feathers with the above mentioned defects appear they should immediately be pulled out to permit new feathers to grow in which usually come in properly. Birds of the white varieties, especially, require shade at moulting time. The plumage will be whiter and freer from brassiness as a result.

If the yards are devoid of green stuff and lacking in natural shade, means should be adopted for providing the proper conditions. Shelters can be constructed that serve the purpose well. These may be constructed of any old material. A framework of lath or wire netting over which is laid branches or weeds affords ample protection. The ground underneath may be spaded up to afford a wallowing place. Sow rape or other green stuff in the yard.

The rations for the moulting fowls should not be the same as when feeding for eggs or meat. The rations should not be so balanced that eggs or flesh, instead of feathers, will be produced. Food of a heating or fattening nature should be eliminated almost entirely from the rations of the moulting fowls. Stimulating food, also, should be excluded, as egg production and moulting are both a strain and we should not permit both to be carried on at the same time, for harm will surely result.

Of the whole grains, wheat and oats are probably the best to feed at this time. A mash, consisting of equal parts of bran, corn meal and wheat middlings and about one-tenth of linseed meal is very beneficial in the growth of new feathers. When the mash is fed moist, buttermilk or skimmilk, when it can be procured at a reasonable price, should be used in mixing it together. Sunflower seeds afford a valuable addition to the rations of the moulting fowls. It should consist of about one-twenty-fifth part of the whole ration. Sunflower seeds tend to bring out the gloss in the plumage and therefore is valuable in feeding show birds.

The moulting period is a good time to weed out all the undesirable hens. The moulting process will show up all the hens that are lacking in vitality—that have not the constitutional vigor necessary for proper breeding condition and productiveness. All the hens that become excessively weakened during the moult should be culled out and put on the market. In any event, they should not be given a chance to enter the breeding pens. The hens that moult easily and with very little lowering of vitality are the ones to constitute your breeders another season.

OTTO E. HACHMAN.

Made in Canada

ENTERPRISE Steel
Monarch Range

MADE of finest steel plate, asbestos-lined, with every practical time-and-labour-saving improvement yet invented, the Monarch is truly a "king among ranges". Strong, handsome, durable, economical of fuel, it will give perfect satisfaction for many years of daily use. For coal or wood.

Valuable New
Fur Style Book
FREE

Again, with the return of winter your attention will be centered on the fur styles. You will want to know what styles are most favoured by the fashion leaders of the world. Some most entrancing styles have been created for this coming season. The master artists of London, Paris and New York have excelled their previous successes in the production of fur styles. In order that you might be able to acquaint yourself with the charming fur fashions they have conceived we have produced a valuable style guide. Our big Fur Book is crowded from cover to cover with photographs of hundreds of sumptuous furs, coats in Persian Lamb, Hudson Seal, etc., Muffs, Stoles and Cravats in many styles and many furs. The Book is a wonderful fashion guide. And not only that—it's the key to economy in fur-buying for it offers the beautiful fur pieces at surprisingly low prices. In whatever part of Canada you live you should not be without a copy of this book. It's yours for the asking. Don't delay—Write for your copy today—it's free.

1954—Cinnamon Wolf Neckpiece, full animal style; finished with head, paws and large full tail; made from selected skins; beautifully lined and finished **$25.00**

1351—Black Fox Neckpiece, made from best quality skins; two full skin animal style, finished with two heads, two tails and paws; beautifully lined and finished **$40.00**

IN THE WOODS

By Frederick G. Scott

This is God's house—the blue sky is the ceiling,
This wood the soft green carpet for His feet,
Those hills His stairs, down which the brooks come stealing
With baby laughter, making earth more sweet.

And here His friends come, clouds, and soft winds sighing,
And little birds whose throats pour forth their love,
And spring and summer, and the white snow lying
Pencilled with shadows of bare boughs above.

And here come sunbeams through the green leaves straying,
And shadows from the storm-clouds over drawn,
And warm, hushed nights, when Mother Earth is praying
So late that her moon-candle burns till dawn.

Sweet house of God, sweet earth, so full of pleasure,
I enter at thy gates in storm or calm;
And every sunbeam is a joy or pleasure,
And every cloud a solace and a balm.

FOURTH ANNUAL CONVENTION OF THE NEW BRUNSWICK WOMEN'S INSTITUTES, ASSEMBLY HALL, ABERDEEN SCHOOL, MONCTON, OCTOBER 2-3-4, 1917.

Tuesday Afternoon, October 2nd.

Presiding—Miss Hazel E. Winter.

8.30—"Cheering Our Soldiers".

9.00—"Child Conservation", (Illustrated). Mrs. H. W. Parsons.

LABOR-SAVING DEVICES FOR THE HOME

Miss Eadie's exhibit of "Labor-saving Devices for the Home" at the Women's Convention held in the Manitoba Agricultural College, February 16th, last, was most interesting.

Grouped around the big Assembly Hall were some twenty girls, students of the college, each exhibiting some one device to save labor. Here is a list of the articles shown:

1. Wooden spoon, for use in cooking acid foods; will not tarnish.

2. Spatulas, 2 sizes; these are soft flat knives used for scraping bowls, slipping pies, etc.

3. (a) Measuring cup. Each cup holds exactly 16 tablespoons.
(b) Regulation tablespoon.
(c) Regulation teaspoon.
Three teaspoons equal one tablespoon. Sixteen tablespoons equal one cup.

4. Home-made shelf—on hinge, so it will open and close. To be placed behind stove to hold extra pans, or be next sink to hold extra dishes.

Peaches

are the most valued treasure on the preserve shelf.

Lantic pure Cane Sugar, with its fine granulation, is best for all preserving.

10, 20 and 100-lb. sacks
2 and 5-lb. cartons

Send us Red Ball Trade-mark for free copies of our three new Cook Books.

"Pure and Uncolored"

LIV

5. Blocks of wood to place under bed posts to raise bed higher during sickness. Makes the nursing easier.

6. Pully clothes line—Pulley costs 25c, wire line 25c.

7. Vacuum cleaner—Small hand size costs $7.00; sold by Reeves, Melford, Conn.

Cupboard for articles used in keeping the house clean. On a shelf where all bottles, such as furniture polish, metal polish, wood alcohol. Beneath was a place to hang each mop, broom, and dust pan. The carpet sweeper stood up on its side so as not to flatten the bristles; the broom hung upside down.

9. Design for farm woman's office. This contained a plain table, chair, waste paper basket. On the table stood a box containing 1,000 tickets. These can be bought anywhere for 75c. a thousand. On these cards were kept family accounts. One section was for recipes. Some kept count of linens, contents of pantry, things needed. In fact, anything the housewife wanted to remember. On the table also was a flat basket holding things of the week, like bills, receipts, letters to answer, etc. On a shelf above were three files to hold accounts, correspondence and clippings.

10. The next exhibit was a plan for an ideal kitchen. On one side of the room were the things used in preparation of a meal—ice box, then kitchen cabinet, then stove and table. Then came the dining room door. On the other side of the room were things used in clearing away the meal—china cabinet and kitchen sink, with its draining table each side, one for dirty dishes and one for clean.

11. Next came a vacuum sweeper—used like a carpet sweeper.

12. A white kitchen stool that screwed up and down to the required height. This one is sold by Shander and Fisher, and costs $5.40. An old piano stool would do as well. This is useful to sit on when ironing or peeling vegetables.

13. A schedule or plan for a day's work in the home. Although the day runs from seven a. m. to seven p. m., the work is so planned that the housekeeper has three hours off each afternoon. This makes a nine-hour work day. Long enough for any one.

14. Next came asbestos holders for lifting things off the stove.

15. A small towel on a loop; the loop is of tape, and slips over the apron belt at the right side; very useful when cooking to wipe the fingers on.

16. A laundry cupboard holding all things needful for wash day and ironing day.

17. Adjustable table. The top could be raised or lowered to suit the size of the worker.

18. Stainless steel knives. They sell for $9.00 per dozen.

19. Sliding larder; to send food down to the cellar to keep cool—a dumb waiter.

20. Porch larder, screened and holding deliveries or other food, cool and away from flies.

21. Fireless cooker, home made. Just a tight box, with a lid on a hinge and plenty of loose excelsior. The simplest device of them all. Just bring the food to the boiling point, cover with pot lid, and pack in the excelsior, with more excelsior packed down on top. Shut the lid, and food will keep on cooking.

22. A kitchen table on legs for use in cooking. Gather materials on it, mix them, put on the stove, then push table and dirty dishes over to the sink. It saves many steps. The top should be of glass or oilcloth.

23. Dinner wagon—table with shelf to carry dinner into dining room and then use to bring out the dirty dishes.

2 . Window larder—made of frame work of wood to fit an open window. Each side is covered with wire screen. One side opens with a door. Daily "left overs" are here kept cool and fly-proof.

Over in another building merchants were showing: Steam cookers, by which a whole meal can be cooked over one little lamp; manufacturer's fireless cookers that will roast meat or bake bread, cook pies or brown anythin; gasoline engines running in washing machines.

Before the exhibit closed, Miss Eadie read a most interesting paper on the value of these in the home.

THE BEN DAVIS APPLE

By Peter McArthur in 1916 Agricultural War Book.

To-day I was tricked into praising the Ben Davis and I culled my choicest adjectives in an attempt to do it justice. And now that I know it was the Ben Davis I was praising, I am not going to take back a word. Instead, I am going to add to them.

My change of heart is due to Charles M. MacFie, of Appin, Secretary of the lGencoe Apple Growers' Association. When I was calling on him he invited me to sample a new preserve his wife had been putting up. He went to the pantry and brought out a sealer filled with something faintly ambertinted and delicately translucent. It looked like citron or like especially successful pear preserves. While he was getting me a dish of it, my mouth watered in anticipation, for it certainly appealed to the eye. I

Spanking Doesn't Cure!

Don't think children can be cured of bed-wetting by spanking them. The trouble is constitutional, the child cannot help it. I will send **FREE** to any mother my successful home treatment, with full instructions. If your children trouble you in this way, send no money, but write me to-day. My treatment is highly recommended to adults troubled with urine difficulties by day or night. Address

Mrs. M. Summers
BOX 309 WINDSOR, Ontario

tasted it. Superb! I thought it was pear preserves, though it was better. Instead of the flat taste often noticed in pears, it had a faint sub-acid flavour that made it perfect.

When I had finished my eulogy he told me as gently as possible, so as to avoid sock, that what I was eating was preserved Ben Davis apple. It seems that this apple has been masquerading all these years. Instead of arousing contempt as an eating-apple, it should be ranking with the pear as a preserving fruit. He gave me a sample from another sealer which contained the same kind of preserves, except that the apples were not peeled. The choicest flavours are just beneath the skin and it was even better than the first, though not so attractive in appearance, and the skin was so tough that it had to be rejected. But it was fit for a king of the canners. I naturally asked Mrs. MacFie for the recipe, and here it is:

Peel and core the apples and cut each into about twelve slices. Place in a preserving kettle and add two cups of sugar for each quart of preserves. Cover with boiling water and then let the preserves boil in the covered kettle until the apples become transparent. Then seal away while hot.

SOME APPLE RECIPES

Brown Betty.—One cup of bread crumbs, 8 sliced apples, ½ cup of molasses, ½ cup of cold water; butter a baking dish, put a layer of crumbs, then a layer of apples, sprinkle with cinnamon and sugar and dot with bits of butter; repeat until the dish is full; insert a knife in several places and pour in the water and molasses. Set in a pan of hot water and bake for fortyfive minutes. Serve hot with cream or hard sauce.

Apple Catchup.—Quarter, pare and core 12 sour apples. Put in a saucepan, cover with water and let simmer until soft; nearly all the water should be evaporated; rub through a sieve and add the following to each quart of pulp; 1 cup of sugar, 1 teaspoon of cloves, 1 teaspoon of mustard, 2 teaspoons of cinnamon, and add 1 tablespoon of salt, 2 cups of vinegar, and 2 grated onions. Bring the catchup to a boil and let simmer gently for 1 hour. Bottle, cork and seal.

Apple Charlotte.—Soak ½ box of granulated gelatine in ½ cup of cold water for half an hour. Whip 1 pint of cream and set on ice; add ½ cup of powdered sugar, a tablespoon of lemon juice and 2 good sized apples, grated. Dissolve the gelatine over hot water and strain into the mixture; stir quickly and pour into a mould. Set on ice to chill, and serve.

Apple Marmalade.—Pare, core and cut into small pieces coarse-grained apples. Allow 1 lb. of sugar to each lb. of apples. Add enough water to dissolve the sugar, and boil until thick; add the apples and boil until tender; pass through colander; add the juice and grated rind of a lemon to every 4 lbs. of fruit. Boil again until thick and put up in jars or glasses. Cover with paraffin. Crab apple marmalade may be made in the same way with the lemon omitted. When cold, it should be cut like cream cheese.

THE CARE OF THE GROWING CHILD'S TEETH.

By the end of the second year, the baby should have his milk teeth complete and until the sixth or seventh year, when the permanent set will begin to appear, these teeth must serve all the purposes that the final set will serve later. Since this is the time the child is learning to chew his food, a process necessary not only for proper digestion but for the strengthening and developing of his jaws and for the proper growth of the permanent teeth, it is important to keep the first teeth in the best possible working order. The condition of the teeth is a fair index to the general health of the child.

Until the child is old enough to use a toothbrush himself, the mother should wash his teeth every day; but as early as possible the child should learn to care for his own teeth. If the teeth can not conveniently be cleaned after each meal, the mouth may at least be rinsed. Children should be taught that it is of special importance to wash the teeth and mouth after eating nuts, or any sweet, sticky or pastry food. The teeth should be carefully cleaned at bedtime since the fermentation of food particles left in the mouth, which leads to the decay of the teeth, proceeds more rapidly at night, when the mouth is still.

The child should be taught to brush the teeth from the gum downward or upward toward the cutting edge. When the teeth are brushed crosswise, the tendency is to push whatever is on them into the cracks and crevices of the teeth or under the edges of the gums. The inner surfaces of the teeth should also be brushed up and down, and the grinding surfaces should be scrubbed in all directions; after the scrubbing is finished, the mouth should be thoroughly rinsed with warm water.

Some hard food like a stalk of celery or part of a ripe juicy apple eaten at the end of a meal scours the surface of the teeth and leaves a fresh clean taste in the mouth.

Children should be taken regularly to a good dentist once or twice a year after the first set of teeth is complete. If cavities appear, they should be filled with soft fillings, and each tooth should be saved as long as possible. If the temporary molars are extracted befort the sixth year, molars come in, the latter will be apt to crowd forward into the space left vacant, and when the later teeth come they will be pushed out of their regular places, destroying the natural line of the mouth. The first molars furnish the grinding surfaces necessary to proper chewing of the food. If they fall out too soon, the child is hardly able to chew hard or tough food, and is likely to swallow such food in chunks.

The care of the child's first teeth is important also, because the health of the permanent set is largely dependent upon that of the first set. The

I KNOW A WOMAN'S SUFFERINGS

I am a woman.

What I have suffered is a far better guide than any MAN'S experience gained second-hand.

I know your need for sympathy and health.

And the treatment that gave me health and strength, new interest in life, I want to pass on to you, that you, too, may enjoy the priceless boon of health.

Are you unhappy, unfit for your duties? Write and tell me how you feel and I will send you ten days' FREE trial of a home treatment to meet your individual needs, together with references to women in Canada who have passed through your troubles and regained health; or you can secure this FREE treatment for your daughter, sister or mother.

If you suffer from pain in the head, back, or bowels, feeling of weight and dragging down sensations, falling or displacement of internal organs, bladder irritation with frequent urination, obstinate constipation or piles, pain in the sides regularly or irregularly, bloating, dyspepsia, extreme nervousness, depressed spirits, melancholy, desire to cry, fear of something evil about to happen, creeping feeling up the spine, palpitation, hot flashes, weariness, sallow complexion, with dark circles under the eyes, pain in the left breast or a general feeling that life is not worth living, I invite you to send to-day for my complete ten days' treatment entirely free and postpaid, to prove to yourself that these ailments can be easily and surely overcome at your own home, without the expense of hospital treatment, or the dangers of an operation. Women everywhere are escaping the surgeon's knife by knowing of my simple method of home treatment, and when you have been benefited, my sister, I shall only ask you to pass the good word along to some other sufferer. My home treatment is for all,—young or old.

Read My FREE Offer:

To Mothers of Daughters I will explain a simple home treatment which ... and effectually dispels ... irregularities. ... young women, and restores them to ... and health. ... about your daughter. ... nothing to give my method of home treatment a complete ten days' trial, and if you wish to continue, it costs only a few cents a week to do so, and it does not interfere with one's daily work. ... asking for! Write for the free treatment suited to your needs, and I will send it in plain wrapper by return mail. Cut out this offer, mark the places that tell your story, and return to me. Write and ask for the free treatment to-day, as you may not see this offer again. Address:

DIARRHOEA and VOMITING

CURED BY

DR. FOWLER'S

Extract of Wild Strawberry.

The pain and suffering, the weakness and oftentimes collapse associated with an attack of diarrhoea, especially when violent vomiting occurs, make it a disease to be dreaded, and for which prompt relief and a ready cure are greatly to be desired.

The salutary action of Dr. Fowler's Extract of Wild Strawberry in giving almost instant relief from the pain, checking the too frequent and irritating stools, settling the stomach and bracing up the weakened heart, render it without a peer for the treatment of all bowel complaints of young or old.

Mr. James G. Vandusen, Medora, Man., writes: "We have used Dr. Fowler's Extract of Wild Strawberry, and have found it to be the most satisfactory remedy of its sort.

I was troubled with diarrhoea and vomiting for a long time. At last I purchased a bottle of your grand remedy, and after I had used but a quarter of it I was completely cured.

Under no circumstances would I be without a bottle of Dr. Fowler's Extract of Wild Strawberry."

"Dr. Fowler's" is an old and reliable remedy, having been on the market for the past 72 years.

You do not experiment when you buy it.

Refuse substitutes. They may be dangerous.

Price, 35c.

Manufactured only by The **T. Milburn Co., Limited.** Toronto, Ont.

St. Isidore, P. Q., Aug. 18, 1894.
Minard's Liniment Co., Limited.

Gentlemen,—I have frequently used MINARD'S LINIMENT and also prescribe it for my patients always with the most gratifying results, and I consider it the best all-round Liniment extant.

Yours truly,
DR. JOS. AUG. SIROIS.

second teeth are much larger than the first, and consequently need more room in the gum. For necessary development the jaws must be given plenty of exercise. Consequently the child should have a mixed diet, including some hard food which he can not swallow without chewing. Toast, crusts, hard crackers, certain fruits like apples, salad, vegetables, and meats should provide the food elements needed for healthy teeth if the child is thriving.

RELIEF AT LAST

I want to help you if you are suffering from bleeding, itching, blind or protruding Piles. I can tell you how, in your own home and without anyone's assistance, you can apply the best of all treatments.

PILES TREATED AT HOME

I promise to send you a FREE trial of the new absorption treatment, and references from your own locality if you will but write and ask. I assure you of immediate relief. Send no money, but tell others of this offer.

HOW TO MAKE APPLE CIDER VINEGAR

The season for making cider vinegar is approaching. See that your press is in good order. If you have no press, by all means order it in plenty of time to assure its being on hand when the apples are ready. A government bulletin gives the following excellent instructions for making high-class apple cider vinegar:

When possible, select such lots of apples as contain the most sugar. Do not use unripe fruit. The apples should be clean. All rotten fruit, moldy grass, sticks, and leaves should be removed. Wash the dirty apples but do not wash the clean ones, as you may wash away too much of the yeast.

Making the Cider

The grinder and press should be clean, if not make it so. Grind the apples as fine as possible and press slowly but firmly. Do not add water to the pomace with a view of obtaining a "second pressing," as such second pressing does not contain enough sugar to make good vinegar. Allow the freshly pressed cider to stand for one or two days in order that the sediment may settle out. When a large quantity of cider is made at one time it is a good plan to have a large receptacle into which the cider may be run for settling. On a small scale barrels may be used for the purpose. Keep the cider covered while settling. As soon as the cider is clear it is ready for the fermenting barrels.

Alcoholic Fermentation

Select, if possible, clean whisky or grain alcohol barrels; these will need but little cleaning, as the acohol they may hold does not interfere. All other barrels should be thoroughly cleaned with warm water and rinsed with scalding hot water. Use plenty of water. Do not sulphur them. Do not use barrels which have contained paint, oils, turpentine, wood or denatured alcohol, as it is impossible to clean them.

Place the clean barrels in the cellar or other places selected for the purpose and fill about three-quarters full of the settled cider. Do not add sugar, water, or any other substance. Do not add '.mother" or vinegar at this time.

The bungholes should not be closed, but should be loosely covered with a double thickness of cheese cloth tacked in place.

If the cider is made during a period of warm fall weather there will be no difficulty experienced by the failure of the fermentation to start promptly. On the other hand, if the cider is cold at the time it is placed in the barrels to ferment, a starter should be added to start the fermentation.

The starter may be made by withdrawing about three gallons of the cider from the barrel and warming this portion to a temperature of 85 to 90° F., and then keeping it in a warm room, protected from dust and dirt, until active fermentation has been going on for two or three days, at the end of which time it is returned to the barrel and mixed with the rest of the cider by shaking.

If there are any barrels of cider made earlier in the season, in which fermentation started promptly and which are still in active fermentation, five gallons from one of these zarrels may be used as a starter.

As soon as fermentation has started the barrels will need no further attention except to see that they do not get too cold until fermentation is completed. This will be in about six months.

Acetic Fermentation

When the alcoholic fermentation is completed, which may be told by the fact that the bubbles of gas are no longer given off (told by placing the ear to the bunghole; the liquid being still), the now hard cider should be carefully drawn off into clean barrels so as not to disturb the sediment. Fill the barrels only about three-quarters full. Add to each barrel from one to two gallons of good finished vinegar containing "mother" and keep as near a temperature of 65 to 75° F. as is possible.

Block the barrels so that they will remain perfectly still. The bungholes should be up and open, but covered with a small piece of well-painted screen to keep out the flies.

Allow the barrels to remain until 4.5 to 5 per cent of acid is produced. This will require from 12 to 18 months.

Aging

Draw off the vinegar and place in barrels made sweet and clean by a thorough washing and scalding. Fill the barrels full, drive in the bung, and place the barrels in a cool cellar for two or three months to age.

The vinegar is then ready for use or for the market.

Causes of Failure

The principal causes of faiulre are summed in the following don'ts:

Don't use green apples; they are deficient in sugar.

Don't use dirty or decayed apples; they contain foreign ferments.

Don't add water; this constitutes adulteration.

Don't use any but perfectly clean barrels.

Don't add vinegar or "mother" until the alcoholic fermentation is complete; vinegar or "mother" interferes with alcoholic fermentation.

Don't try to conduct the alcoholic fermentation below 50° F.

Don't let the temperature of the cider go below 50° F. until the alcoholic fermentation is complete.

Don't fill barrels more than three-quarters full.

Don't sell vinegar without labeling it.

Don't forget that cleanliness is essential to success.

Don't allow vinegar to come in contact with any metal.

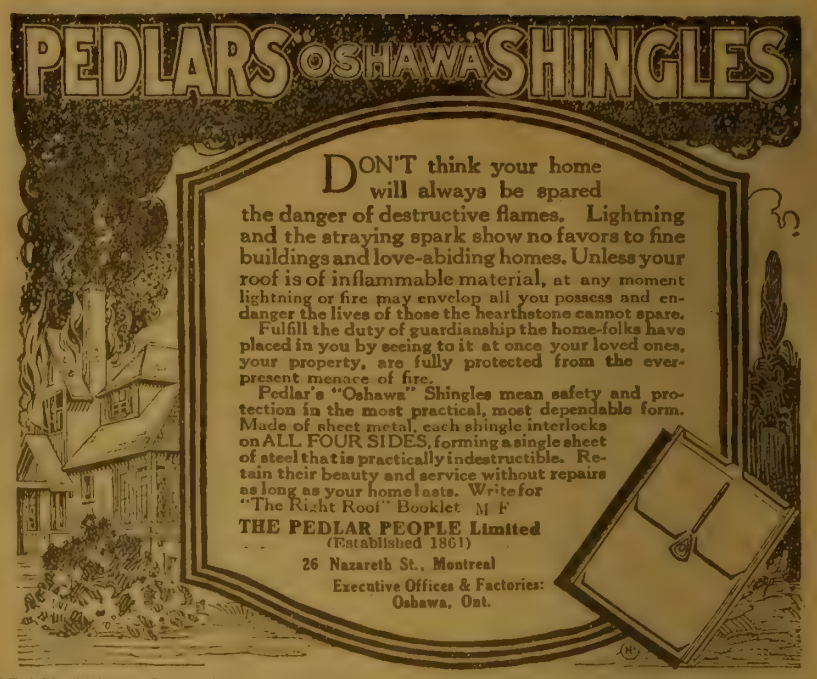
While the directions here given may seem rather lengthly, they are sure to produce a vinegar of standard strength and of good quality. It is true that some of the details of the method may be disregarded, but the quality of the product may suff as a result.

TRAINING THE CHILD IN TRUTHFULNESS

Anyone who has not lived with an observant, clear-minded child has missed an important part of moral education. When a child is quite truthful, when he has not been frightened into dishonesty for his own protection, nor taught to think it the usual way of the world by careless elders, the slightest deviation from the straight line of truth appears as a distortion in the mirror of his mind. When we view ourselves through those candid eyes we are surprised to find how many of our customary actions will not stand the test. If it is a mother that makes this discovery she is troubled. She knows that dishonesty in its various forms is the curse of the modern world, and she hopes that her little ones will grow up to be hearers of truth. How then, shall she square her conduct to their simple but inflexible standards? If she does not justify herself in their eyes they will think that falsehood cannot be always and entirely wrong.

"Mother," said a wee girl, who was watching her mother dress in the evening, "I shouldn't think you would feel like going out to-night."

"Why not, dearie?"



PEDLARS OSHAWA SHINGLES
DON'T think your home will always be spared the danger of destructive flames. Lightning and the straying spark show no favors to fine buildings and love-abiding homes. Unless your roof is of inflammable material, at any moment lightning or fire may envelop all you possess and endanger the lives of those the hearthstone cannot spare.
Fulfill the duty of guardianship the home-folks have placed in you by seeing to it at once your loved ones, your property, are fully protected from the ever-present menace of fire.
Pedlar's "Oshawa" Shingles mean safety and protection in the most practical, most dependable form. Made of sheet metal, each shingle interlocks on ALL FOUR SIDES, forming a single sheet of steel that is practically indestructible. Retain their beauty and service without repairs as long as your home lasts. Write for "The Right Roof" Booklet M F

ARE YOU LOSING YOUR GRIP ?

Dr. Cassell's Tablets are the remedy to restore your Energy, and to rebuild Health and Vitality

If anyone who feels weak or languid, whose vitality has been lowered from any cause, whose nerves are overstrained or "jumpy," will take a course of Dr. Cassell's Tablets, he or she cannot fail to be astonished at the wonderful new health and vigour that will follow and follow suickly. Dr. Cassell's Tablets are an ideal brace-up. They strengthen the nervous system throughout, invigorate all the bodily functions, give "Spring" and "Grip" and fitness even to the weakest. And there is no dope in them.

A free sample of Dr. Cassell's Tablets will be sent to you on receipt of 5 cents for mailing and packing. Address: Harold F. Ritchie and Co., Ltd., 10, M'Caul-street, Toronto.

Sr. Cassell's Tablets are the supreme remedy for Dyspepsia, Kidney Troubles, Sleeplessness, Anaemia, Nervous ailments, and Nerve paralysis, and for weakness in children. Specially valuable for nursing mothers and during the critical periods of life. Price 50 cents per tube, six tubes for the price of five, from Druggists and Storekeepers throughout Canada. Don't waste your money on imitations; get the genuine Dr. Cassell's Tablets.

Proprietors, Dr. Cassell's Co., Ltd., Manchester, Eng.

NEEDS NO PAINTING

Amatite stands alone in the ready roofing world. It is the one roofing you don't have to paint. Once laid, it will last for years without any attention from you. For sidings and steep roofs it is supreme. If you could only see how it is made—see the tough, fibrous felt, the dense, non-volatile saturating compound that keeps it water-tight, you would understand our claims. Try some.

A Roofing Triumph

The durability of Amatite is only one of its fine points. The same structural feature which makes it unnecessary to paint Amatite, gives it a distinctive and beautiful appearance. We refer to its sparkling, mineral surface. Improves the appearance of any building. The best buy in the ready roofing market.

Butter Parchment at Farmer Office

"When auntie was here this afternoon and wanted you to go to the lecture, you were afraid the cold would make your neuralgia worse."

A mother refused an invitation to what she thought would be a prosy affair, giving as her "excuse" that she couldn't leave the children in the evening. A small son listened with absorbed interest to the polite regrets expressed on both sides. When the visitor was gone, he said: "If you wanted to go so much, mamma, why didn't you have cousin Laura stay with us, like you do when you and papa go to the concert?"

Some of the children's most puzzling questions are about the disagreeable visitors. Why do we make them welcome or ask them to come again? Fortunately this matter can be explained. The most tiresome visitor means a kindness when she comes to see friends, and must be received in a kindly spirit.

From the beginning of the child's training, kindness must be made the foundation for politeness. Thus the child may be taught tact. It is certainly necessary while teaching our children to tell nothing but the truth, to remind them that the whole truth is not always needful. But kindness will not explain many of our "polite" lies. When the child has heard us say, in the privacy of the family, that Miss So and So's singing was wretched and then afterwards stand by while we assure the singer that we enjoyed her singing so much, his private opinion of us is not likely to be flattering.

More blamable still are the cases where deception is practiced in the home; the questionable book slipped out of sight in the virtuous mending oasket, the expenditures concealed, the forbidden visits hidden. These things seem to make an atmosphere of which the child becomes conscious.

Even varying treatment of the child's own misdeeds is noted. How many have heard of the boy who came to the table with tousled hair and when his mother said: "You know I never allow you to come to dinner without brushing your hair," replied: "Yes, you did once, mother."

Perhaps the limitations of humanity will not permit such unvariableness as a child demands, but to look at ourselves in the mirror of the child's mind will help us toward perfect truthfulness.

THE GREATEST ERROR IN FEEDING THE DAIRY COW IS LACK OF LIBERALITY

(Continued from page 568)

less roughage and less concentrates in the production of milk. Deductively, at least, these figures show the value of breeding and the generalization may be made that with increasing productivity and values, the relative percentage of expenditure for feeds, prices remaining the same, decreases, while depreciation, shelter and interest increases.

Dairymen have been more interested in the prices of their products than in the cost of production, apparently forgetful of the fact that profits accrue to the business dairyman as they do to the manufacturer. First, from a price for his product sufficient to more than cover the average cost of production; secondly, from cheapening the cost of production sufficiently to obtain a profit. The latter method offers the greater opportunity to the dairyman with a well orgasized business, one who will study and apply economics to the industry.

The time of the year during which the major part of the milk is produced may materially affect the cost of production as well as income from the dairy. Milk can be produced much more economically during the winter when stall feeding is necessary. There are other items to be taken into consideration. Labor conditions in summer often make it difficult to properly care for the stock; during the winter, stock, even though dry, must be fed and cared for; a small amount of feed and care additional to that required for maintenance may prove profitable, and, lastly, prices for dairy products are so much higher in winter than in summer that the total income per cow is larger and net profits more satisfactory, provided the milk flow is produced during the winter months. The strongest argument in favor of winter dairying is its adoption by the most capable dairymen and the constant tendency in the dairy sections towards maximum production during the winter months.

The cost of feed and labor, the cost of the cow, and all other items of cost of maintenance determine the quantity of the product a cow should yield in order to give the owner a profit. And as the cost of feed, labor and the investment per cow increases or decreases, in such proportion must the efficiency of the herd increase, price of product remaining the same, to give a profit to the owner.

The Worth of a Cow

In order that the cow may be profitable, cow and investment should bear a certain and definite relationship to the product that must be obtained. The question frequently arises: "What is a cow worth that gives a certain quantity of milk, and how much milk must a cow of a certain value give before she makes a profit for the owner?" This question may be answered definitely, providing the cost of feeding, care, etc., is known, and the average price received for the product can be ascertained. It can only be answered exactly from a productive standpoint. It is imperative that cows of high values, to be pro-

IRON

fitable, should be more productive than the average. From a productive standpoint, a farmer can not afford to pay $80 to $100 for a cow unless she will produce 5,500 to 5,900 pounds of milk per year. While the value of the calf and the manure may enter into the consideration of ordinary farmers, yet the dairy farmer, who gains eighty per cent. of his income from dairy business, must consider only the productive capacity as related to the annual profits.

One of the most difficult tasks of farm managers is to keep all capital employed in such a way as to produce maximum profits. The investment of money in live stock which do not bring a return commensurate with the cost of maintenance and capital invested is a common source of loss. It is easy to pick out a herd of cows at $70, or over per head, that will not give an adequate return for the cost. The principal cause for such loss is that prices have been paid for the stock on the basis of gross income without regard to maintenance cost.

The Investment in Dairying

The same economic forces apply to the investment of capital in cows as to its investment in lands—that is, as either increase in value or are purchased at high prices, they must, to be profitable, become more productive because of gross increase in interest and depreciation charges.

Both interest and depreciation are very high when cows are purchased at $100 per head or over. The annual charges are then $15.58 or more per year, as compared to $4.35 for the $40 cow. The average cow producing 4,000 pounds of milk annually would, under such circumstances be kept at a loss of more than $5 per year, and would not only be valueless from a productive standpoint, but would represent a liability to the farm, rather than an asset, unless the value of the manure and of the calf were considered sufficient to offset the loss occasioned by her use.

With an average annual return of $1.20 per hundred pounds, or twenty-seven cents for butter-fat, and with food and labor requirements at the prices determined, a cow has no value, based on productivity, until her annual product is between 4,500 and 5,000 pounds of milk. When 5,000 pounds of milk are produced annually a cow has a value of $25. That is, the difference between the sum received for her product and the cost of obtaining it capitalized permits of a valuation of $25 on which interest must be earned and a sufficient sum set aside to cover depreciation. As the annual product increases over 5,000 pounds, the productive value of the cow increases very rapidly. When 6,000 pounds are produced annually, her value is more than two and a half times that of a cow producing 5,000 pounds annually. The cow giving 10,000 pounds of milk is worth $230 as a producer. Her breeding value is to be added onto this sum. Obviously, a cow giving 10,000 pounds of milk annually has a higher value than that based upon her productivity, for dairymen everywhere desire to build herds on just such stock, and demands for young stock would swamp any dairy farmer.

No better illustration can be made of the value of productive cows than the comparison between the cow giving 10,000 pounds and the one giving 4,000 pounds. The former represents a capital investment that is extremely productive, that pays for all she receives and gives an ample return and protection on her own value; the latter nets a loss of more than $5 per year.

Placing the dairy farm upon a profitable basis means putting brains and energy into the business; making it a business, just like manufacturing any other marketable product, and making it at the lowest possible cost with the most profitable stock.

HEART TROUBLE

Caused Dizziness, Weakness and Smothering Spells.

When the heart becomes affected, there ensues a feeling of a choking sensation, a shortness of breath, palpitation, throbbing, smothering sensation, and dizziness and a weak, sinking, all-gone feeling of oppression and anxiety.

On the first sign of the heart becoming weakened Milburn's Heart and Nerve Pills should be taken, and you will find that they will give prompt relief and soon effect a complete cure.

Mr. John Doucette, Eel River Crossing, N.B., writes: "I suffered greatly from heart trouble which caused dizziness, weakness and smothering spells. I used a great deal of doctor's medicine but received no benefit. A friend advised me to use Milburn's Heart and Nerve Pills, and before I had finished the first box I felt so much better that I got another one, and was completely restored. I highly recommend these pills to everyone suffering from heart trouble.

Milburn's Heart and Nerve Pills are 50c. per box at all dealers, or mailed direct on receipt of price by The T. Milburn Co., Limited Toronto, Ont.

Roof Barns with Paroid

THE choice for roofing narrows down to wooden shingles, metal, and Paroid. The fire risk with wood is too great, and frequent repairs are necessary to insure even reasonably long life. It costs less to lay Paroid than either metal or wood, affords full protection from the weather, checks a fire from falling sparks and embers, and requires no repairs. Roof with

HOW TO HANDLE LAND AFTER HAY CROP IS REMOVED

August and September are months when the dairyman is pretty anxious about the herd. The luxuriant pastures of May and June are no longer available and many have made no provision for the summer months, when the days are hot and the flies are bad. The cows are falling off rapidly in their milk flow and the only thing in sight is the field of young clover and the green oat crop just nicely headed out and looking good for fifty, sixty or more bushels to the acre. But something must be done for the cows or they will soon be dry and thin and the milk revenue will be beyond control. To relieve the situation which shall be used, the young clover, just nicely started on the journey of its second growth, or cuttings from the promising field of oats. The farmer knows that the clover is too young to get the best results from pasturing it, but he hasn't the nerve to touch the beautiful oat crop, and so the young clover is sacrificed. Sacrificed? Yes, because the loss is too great to be viewed in any other light, considering the small amount of actual fodder that will be obtained from it, as compared with that which could reasonably be expected from a properly treated field; and so all over the country field after field of promising clover is being largely ruined before the tender plant is strong enough to stand the trampling of cattle and before the growth is far enough advanced to yield a profitable return.

In almost every case it will be found much better to feed from the oat field or from some other source for a few days and let the clover stand until it gets a foot high. It will then have more substance, will not be so easily broken or crushed and will last the cows much longer than when pastured soon after the hay crop is removed. Rather than pasture the clover field too soon it will be economy to feed hay and grain for two weeks or more in order to give the second growth a chance to get a good start.

It is the practice of many farmers not only to allow the stock on to the land while the second crop is too young, but also to continue the cropping too continuously and too late in the season. When a clover crop is eaten down so that the stock has to bite close to the ground and roots, they should be kept off until the field is sufficiently grown again to provide a good yield. The continual trampling of stock has a tendency to break and damage the crowns of the plant and reduce their vigor. By keeping off the land, excepting when the plant is large and strong enough to produce a good yield, the vitality will be conserved and when a favorable time comes it will then be in a condition to grow luxuriantly.

Late pasturing of the clover field in the fall months should also be discouraged. The plant should be able to secure a little covering to protect it from the winter frost and keep the ground covered so that it will not freeze and thaw so readily in the spring. Again the ground is likely to be soft in the fall and if the stock is allowed to roam over the fields they will do a lot of damage to the land by puddling as well as to the plants by punching them into the earth. Good pastures are a fine thing and worth taking care of, but the treatment that many fields get, after the hay si taken off, is not at all favorable to a good stand next year either for hay or pasture.

Old meadows that are no longer profitable for the hay crop, and there

In the finest households in the land where *baking* results alone are *the* thing that counts, and also in the poorest families where *economy* is an absolute necessity,

THE USSEX MANUFACTURING CO., LTD.

SUSSEX, - - New Brunswick

are many of them, should be plowed light as soon after the hay is off. They will afford no pasture worth while if left until late in the fall, and the time had better be spent in killing weeds and putting the land in good condition for a crop next season. Very shallow plowing will be best for the first operation both for killing weeds and rotting the sod. If the weather is dry this may be allowed to lie and dry out before subsequent cultivation takes place, when it should be thoroughly cut up with a heavy disc and cultivation be continued at intervals until late in the autumn when it should be plowed, and deeper, if intended for a spring crop. If potatoes are to be planted it will be best to apply manure in the fall if possible and work it into the land, as fresh manure is likely to produce scab.

The pasturing of land by stock is too often a haphazard affair, rather than a well planned and crefully carried out progrmme. This is a very poor policy indeed, for land properly prepared and used for this purpose can be made to conserve the interests of the farm as well as any other part if due consideration is given to it and a careful plan laid out and religiously followed.

THE N. B. FARMERS EXCURSION TO THE EXPERIMENTAL STATION

(Continued from page 566)

more men join together and fulfill certain requirements.

The dairy industry is being revived in the province, particular emphasis being laid on quality rather than on quantity.

Mr. Tweeddale also explained the County Agent or District Representative plan, which he and his Deputy, Mr. Reek, are putting into operation in the province. The system has proved a boon to the farmers of other parts of Canada and the United States, and good results are anticipated from the inauguration of this system in the Province of New Brunswick.

The sheep industry for many years on the decline in New Brunswick, is again beginning to come into its own. The large number of inquiries for pure bred ewes and rams, and high grade ewes, that is being received by the Provincial Live Stock Superintendent, Thos. Hetherington, is a sure indication that in a year or two, numerous flocks of sheep will graze the thousands of acres of New Brunswick soil, to which at present time the golden hoof is a stranger.

Prof. G. C. Cunningham, the Provincial Plant Pathologist, announced that he would be pleased to meet

WETTLAUFER BROS., LTD., Toronto, Ont.
DOUGLAS FULLERTON CO Dartmouth, N.S

farmers interested in potato growing in the fields, where he is conducting some experiments. What he would like to tell the farmers, could be explained much better in the fields, where they would have the opportunity of seeing for themselves the necessity for controlling potato diseases and using the best seed available.

B. Leslie Emslie, Fertilizer expert for the Dominion Government was present, and conducted a party of farmers interested in fertilizer tests, through the fields where such tests are being conducted.

Seth Jones, Provincial Poultry Superintendent, was kept busy explaining poultry matters in the poultry yards.

W. S. Blair, Superintendent of the Horticultural Station, Kentville, N. S., conducted a party of horticulturists through the new orchards and answered question in regard to fruit growing.

The Provincial Live Stock Superintendent, Thos. Hetherington, gave an excellent talk and demonstration on the points to look for in beef and dairy cattle. With a number of pure bred and grade animals of both classes, he was able to readily show and contrast the various points under discussion.

Mr. Hetherington is a New Brunswick boy, who made a good record in his college career, and who has accepted the important position he now holds, determined to put the best that is in him into his work. He made his first appearance before a New Brunswick farmers' audience on Labor Day. His practical method of handling his subject, gave him a well merited status in the opinion of the farmers of the province.

The farmers' field day afforded a pleasant day's outing for the farmers and their families. They will also be in a position to better interpret the published reports, when they reach them, of the final conclusions deducted from the experiments now being conducted on the farm. Inadvertedly they will strive to follow some of the best and most applicable methods and thus the Experimental Station will be accomplishing the aims for which it was organized.

GOOD GRANARY ON EVERY FARM IS VERY ESSENTIAL

There are many farms without a good granary. In these days of high priced cereals and products of all kinds one should reduce the wastes of the farm to the very lowest possible point by providing a suitable place to store the harvest so that the ravages of mice and rats can be entirely controlled and every pound of grain conserved as food for the use of man and beast. A food controller has recently been appointed by the Canadian Government for the purpose of saving all the cereals and meat products possible and in every way to cut out all waste of farm produce. One of the biggest losses on the farm is caused by the destruction of grain by these rodents. Comparatively few farmers are free from loss through this cause, and many are great losers. The aggregate yearly amount of leakage from the grain-bin is very great and with many, no doubt, more than equal to an amount sufficient to furnish protection against this class of vermin.

Granaries that are built in a barn may be rendered proof against rats and mice by covering them on the outside with metal such as galvanized iron. Second hand stuff may sometimes be secured that will answer the purpose just as well as new material. It is very difficult to build a granary entirely of wood, in a barn, that will effectually keep out the rats and mice. It is claimed by some that rats and mice will go through boards made of hemlock but unless these are very thick the pests will get in. It is better to use metal and make a sure job than take any chances with wood only.

Where there is not sufficient room in a barn for a good granary one may be built at some convenient point outside. When this is done it may be so built that rats or mice cannot get into it. To do this the building should be placed two or three feet above the ground, built on a cement wall or heavy posts. If on the former a strip of galvanized iron should be laid on top of the wall and project ver at least four inches on either sides, and turn down a couple of inches which will effectually prevent vermin of this class from securing a foothold or gaining an entrance into the building.

Where the building is set on large posts an ordinary shallow tin pan, large enough to project well over the post may be turned upside down over them which will effectually prevent the rodents from getting in from beneath.

But the building must be completely isolated from other structures, even fences, or steps up into it from the ground or an entrance will be ecected from these sources.

Combination granaries have been built on some farms in connection with pig pens, but ordinarily this plan is not to be recommended unless especially for feeding swine as the upper story, which is usually used for the grain is not convenient for that purpose, unless built on a side hill and any dampness or smell from the pen is not conducive to best results in keeping the grain.

So far as the choice of material is concerned in the building of a granary there is no doubt but that wood is best if protected by a metal covering. Cement would cause deposits of moisture now and then when grain was "sweating" which would be favorable to the development of mould.

The difference between the cost of an all round satisfactory granary and an inferior is so small as to be an insignificant factor when compared with the advantages of the former, that one should not hesitate to secure the former under all circumstances.

LIGHTNING RODS PROTECT BUILDINGS

Investigations made by various agricultural stations and by insurance companies show that lightning rods really do protect. In one of these investigations it was shown that out of 7000 unrodded farm buildings 37 were struck bf lightning, and out of 7000 rodded buildings but two were struck. One fire insurance company paid out, in three years, only $32 in lightning losses on rodded buildings. In every loss reported a careful examination proved that defects in the lightning-rod equipment existed which accounted for the lack of protection.

Eureka Potato Digger

Gets the Potatoes and separates where other diggers cannot

A strong statement, but an actual experience many times, saving growers more than the cost of the Digger. Ask us for the proof.

The Eureka elevator and duplex shaker provide more separation than other diggers. Large wheels and main gears supply ample power. Mostly malleable and steel, avoiding frequent breakage and lost time. Growers report digging 80 or more acres without repairs. High clearance over shovel prevents weeds and vines bunching. Has vine-turner attachment.

6-ft. and 7-ft. sizes; several styles.

SHOW STOCK SALE!

"Minnie Vale of Victoria," another four year old daughter of "Ida Rooker 2nd Vale," has just finished a R.O.P. record of 15.784 lbs. milk and 5.61 lbs. fat, making two daughters in R.O.M. and R.O.P., all showing a much higher milk and fat record than dams. He is also a breeder of show type as proved by his continual winnings in the (get of sire class) at all Maritime Shows.

We can sell a few grand young Bulls by him, different ages, also expect to have a show lot of P. B. and grade females at Halifax, several choice ones to freshen then.

W. M. LEA,
"RIVERSIDE FARM," VICTORIA, P.E.I.

Two Cents a Word.

This department is one of the most valuable in the MARITIME FARMER. At a cost of only 2 cents a word, you can advertise anything you wish to buy, sell or exchange. The aderess must be counted as part of the advertisement and each initial or a number counts as one word. Cash must accompany each order and advertisement must have address on, as we cannot forward replies sent to this office. Copy must be received not later than Friday before the date of issue which will always be found on the editorial page of the proceeding issle. No black faced type or display of any kind will be allowed under this head, thus making a small add as noticeable as a large one. The rate for this column is 2 cents a word, each insertion. THE REGULAR COURSE

AT THE

College of Agriculture Truro, - Nova Scotia

Commences October 31st Next

THIS COURSE offers an opportunity to study the fundamental principles of INCREASED PRODUCTION which, second only to fighting, is the Paramount Need of Canada today and which will be of preeminently first importance after the war. The young farmer who is not in a position to go to the war should not miss the opportunity of Preparation which the course at Truro offers.

Tuition free to Students from all the Provinces of Canada. Write for Calendar to

SUSSEX, N. B.

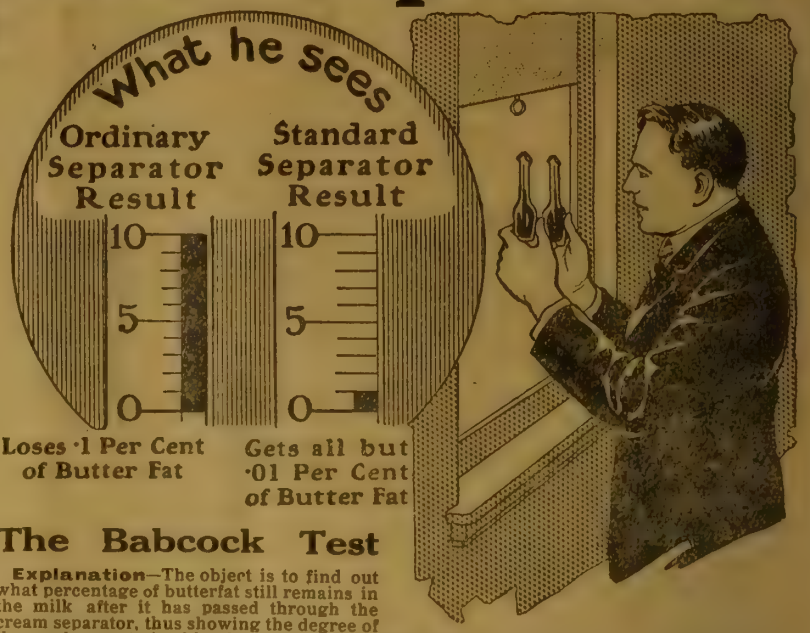
Can Your Cream Separator Meet this Test?

"Are you keeping cows, or are the cows keeping you? The only way to be sure is to weigh and test"—
Farmer's Advocate, April 5, 1917.

The Babcock Test measures accurately the percentage of butter-fat still remaining in the milk after it passes through a cream-separator. In the picture we show two Babcock results as indicated by the measurement tube of the Babcock Testing bottle. The long black column on the first tube in the circle shows the result obtained by testing the milk skimmed by ordinary separators; it shows a loss of .1 per cent butter-fat. The small black mark on the other tube shown represents the extra small loss obtained by the Standard's close skimming which gets all but .01 percent of the butter-fat. In other words, the Standard gets all but one-tenth of butter-fat per 1000 pounds of milk skimmed, while other machines lose a whole pound.

The comparison indicates a clear gain of 9/10 of a pound of butter-fat on every 1000 pounds of milk you skim—if you use the

Standard



The Babcock Test

Explanation—The object is to find out what percentage of butterfat still remains in the milk after it has passed through the cream separator, thus showing the degree of thoroughness attained by the machine. In the circle above we show two enlarged sections of the graduated tubes on the Babcock testing bottles. The black marks show the amount of butter-fat left in the milk after skimming. To find the number of parts of butter-fat remaining in every hundred parts of milk tested, the butter-fat musi be separated from the milk and measured. That is what tbe Babcock test does. A special bottle with a lengthened neck is used. On the neck are marks which tell the percentages. The experimenter wants to get the butter-fat separated and pushed up into the neck where its measurement can be seen By a simple process he does this, and he then knows exactly how well the skimming has been done in the separator. The Babcock test is used by our Government Dairy Schools and in many other countries beside Canada. Standard Cream Separators are tested by this scientific method before they leave our factory.

This saving of cream by the Standard is well worth while for it means an extra profit of about half a pound of butter-fat per cow per week. Multiply this ½ pound saved by the number of cows in your herd, and ask yourself, "Can I afford to lose this extra profit? Will it not pay me to own a Standard?"

Before the Standard goes to you, it must prove its close skimming by meeting the Babcock Tests made by our experts in our own factory. These tests have been confirmed by independent Babcock tests made at the Government Dairy Schools, Ottawa. They all prove that the Standard out-skims other machines.

Do you know how closely your separator skims? You can find out by sending a sample of skimmed milk from your machine to the Government Dairy Schools. Compare the result with the Standard's proven record. It may pay you to discard your old machine for the close-skimming Standard. With a certain number of cows the Standard pays for itself in cream saved within the time you pay for it on our easy payment plan and it will pay you to operate a Standard even if you have only two cows.

The Standard's exclusive curved wing center piece eliminates whipping in the distribution of the whole milk to the discs. This means firm butter. The Standard not only saves cream, but it gives better quality results. If you want sweet, firm, high-grade butter you can have it by using a Standard.

The Standard is entirely made and designed in Canada by Canadians.

Send for interesting literature describing the Standard's low supply can, interchangeable capacity feature, self-oiling system, etc. Tear out and mail this coupon today.

EASY JELLY MAKING

It is as easy to make good jelly as it is to make good apple sauce, only that it takes a few moments longer. If you follow exactly the following rule, you can make jelly of a delicious fineness and color and taste. When you cook the fruit use just a little water, because the water has to be cooked out; the more you put in the more you will have to cook out. Use your over-ripe mussy fruit for jam, but use only the best for jelly.

Thirty-five Minute Jelly.

With many fruits you can make jelly in 35 minutes from the time you put the fruit on the stove until you have the liquid in the glasses. It is easier to do it slower; let the fruit heat slowly then boil briskly until very soft. Hard boiling makes fruit go to pieces and that is what you want. The less time spent in cooking the fruit, the better the flavor of the jelly. Now for the rule.

GRAPES, APPLES, CURRANTS, QUINCES, GREEN GRAPES, GREENISH PLUMS, etc. Fix for the jelly by having them clean. You need never peel anything for jelly as the peel will make the liquid "jell" better and it gives the jelly a better color and flavor. Stem grapes and currants. Bring to a boil and then boil very rapidly until soft; mash them if necessary to make the juice come out. Put the fruit in a bag made from a piece of cheese cloth, cut square and sewed up diagonally so as to form a cornucopia. Fasten the bag to some convenient place to drain, or if in a hurry squeeze the juice out. This gives you a good deal more jelly, if quantity is what you are after, and it jellies quicker if it is pressed some, but the jelly will not be so clear, although it is extremely nice. When the juice has been pressed out or has been dripped out, measure it and put it over the fire. Measure as much sugar as you have juice and put this in the oven to heat. Let the juice come to a quick boil uncovered. Let it boil exactly 20 minutes then add the sugar and let it boil up. Do not cook it two minutes after it boils up again if the sugar is all melted by this time. Skim off any skum and pour into glasses and you are done. Many times the jelly will get hard almost at once, but in some cases it will not be real hard for some days after it has been made, and it is better so, for jelly that hardens at once is apt to get too solid when it is kept any length of time.

Do not cover soft jelly with paraffin until it hardens; when it does, pour melted paraffin over the top to prevent it getting any harder, and to prevent moulding. It can be lifted off when the jelly is wanted for use.

Many fruits will not jelly alone. With these, a mild-flavored but sour apple should be used, half and half, as apples have as much jelly making properties as any known fruit.

You can use apples whole for jelly, simply washing them clean, but quinces should always have the stones removed for these possess a certain property that prevent anything from jellying. Without the stones, this fruit jellies easily and makes one of the most delicious jellies known. The juice from cooked quince parings when added to apple juice, will flavor the apple jelly richly. Peach juice and apple juice is a combination that makes delicious jelly. Also combinations of pineapple and apple, raspberry and currants, and so on.

He Knew

"Why couldn't Eve 'ave the measles, old boundah?"

"Cawn't say that I know. Why?"

"Because she 'ad Adam, old fellow."

REGISTERED TRADE MARK

Official Organ of The Farmers' and Dairymen's Association of New Brunswick, The Nova Scotia Farmers' Association, The Nova Scotia, New Brunswick and P. E. Island Fruit Growers' Associations, The Maritime Stock Breeders' Association, The Maritime Bee-Keepers' Association and The Newfoundland Agricultural Board.

Volume 22. SUSSEX, NEW BRUNSWICK, SEPTEMBER 25, 1917. Number 24.

The Nova Scotia Provincial Exhibition

The Nova Scotia Provincial Exhibition for 1917 was held, as advertised in the columns of the Maritime Farmer, on September 12th to 20th.

Every promise made to the public by Manager M. McF. Hall re the attractions of the big fair was redeemed. The farmers, horticulturists and stock raisers of the Maritime Provinces, brought together their best products from their fields, gardens, orchards, barns and pastures, where they might compare the results of their efforts during the year, glean ideas from each other and infuse a new energy into their work.

The brand of weather was all that could be desired until the near the close of the fair. The attendance was very good, considering that many branches of industry in Maritime Canada are working short handed. Many of our progressive farmers now look upon the Halifax Exhibition as an ideal place to spend their yearly holidays—a place where they can combine business, education and pleasure.

Manager Hall, his efficient staff and the various members of the Exhibition Commission had worked hard to stage an exhibition that would be pleasing to the public. The farmers and other exhibitors co-operated with their best efforts so that the outcome was quite satisfactory to everybody. Matters were run as smoothly as possible. Obnoxious features were elimated from the midway. The professional shark was not allowed to operate on the grounds and upwards of twenty witty gentlemen, pho perhaps had found Halifax Exhibitors an easy prey had to hastily betake themselves to other parts when the management discovered the first clues to shady practices.

Visitors to the Exhibition could find many matters to interest them in the various departments.

THE MINES BUILDING

The mines building was well filled with specimens of the Economic minerals of Nova Scotia and exhibits showing some of the products of the Dominion Iron & Steel Co. The Nova Scotia Steel and Coal Co., and various other coal mining companies operating in the province. Visitors were also interested in the munitions display there staged.

THE WOMENS INSTITUTES OF NOVA SCOTIA

The Womens Institutes Branch of the Nova Scotia Department of Agriculture, under the efficient management of their superintendent, Miss Jennie A. Fraser, conducted canning demonstrations at stated hours in the building occupied by them last year. The display of canned fruits and vegetables and the explicit manner in which Miss Fraser explained how easily the work may be performed, will surely be an incentive to the home-makers of the province to conserve for future use, quantities of delicious vegetables that will come in handy and help to lend variety to the family bill-of-fare during the season when fresh vegetables are strangers to many tables.

The figures given out by Miss Fraser show that a great saving may be effected by canning home grown or even bought vegetables and fruits, rather than by following the practice of purchasing factory canned goods.

The fine Arts and Ladies' Fancy Work Departments, particularly in the latter class, was well up to the displays of previous years.

IN THE MAIN BUILDING

Every available foot of floor space in the main building was occupied. The various booths were well arranged and attractive.

The galleries contained the best and most comprehensive display of the work of school children ever staged in Maritime Canada. It was very interesting to examine the work of the pupils of the many schools that helped stage the display. The work showed that the young of the province are being lead along right lines to future lines of usefulness.

The Live Stock Branch of the Federal Department of Agriculture had their educative displays of eggs and wool on exhibition with competent men in charge, who were indefatiguable in their work of explaining to an interested public the proper methods of caring for and marketing these two important commodities.

THE NOVA SCOTIA AGRICULTURAL COLLEGE

had a well arranged booth conducted by its Department of Chemistry showing:—

(1) Various types of Nova Scotian soil with their analysis.

(2) Specimens of turnips and clover to show effect of liming.

(3) A display of the various commercial fertilizers with their analysis. In this connection the various by-products of N. S. suitable for fertilizer are shown for comparison, both in price and analysis, with the commercial articles.

(4) An exhibit of the numerous forms of limestone and marl, native to our province. Figures showing analysis also accompany these.

(5) Numerous charts setting forth in a concise manner, much valuable informaiton for the agriculturist.

(6) Such simple tests as the titmus test for sour soils and the acid test for limestone, are demonstrated to interested parties.

Objects:

(1) To interest farmers in the raw material of their industry; i. e., in the soil, its ingredients and deficiencies and how the latter can best be remedied.

(2) To give information on the composition and relative value of different fertilizing materials.

(3) To encourage the use of lime and to explain just how it acts; its different forms, etc.

Results have been encouraging. Many farmers have expressed themselves as highly pleased with the character of the exhibit.

THE JUDGES

The awards in the various agricultural and live stock classes were placed by the following judges:—

Heavy Horses—D. J. Greig, Allens Corners, Que.

Light Horses—Dr. J. Hugo Reed, Guelph, Ont.

Ayrshires—Jas. Bowden, Danville, Que.

Jerseys—F. L. Greene, Greenwood.

Holsteins—Neil Sangster, Ormstown, Que.

Guernseys—F. L. Greene.

Beef Cattle—F. H. Reed, Ottawa.

Sheep—F. H. Reed.

Swine—T. H. Mason, Ottawa.

Poultry—W. H. Reid, Kingston, Ont.

Dairy Products—Harvey Mitchell and W. A. MacKay.

Horticultural Products—Geo. H. Vroom, Middleton.

Agricultural Products—S. J. Moore.

IN THE AGRICULTURAL HALL

The Agricultural Hall was filled to its capacity with the products of fields and garden. Many excellent specimens were shown in the respective classes and showed to no small degree the good work that our farmers accomplished during the past season, in their efforts for increased production.

The display of vegetables, etc., from the schools participating in Rural Science work, was the most creditable ever brought together in the Maritime Provinces, and was a clear indication of the hearty manner in which the teachers of the province are co-operating with Superintendent DeWolfe in getting the children interested in matters that will claim their attention when they come to mature years. The exhibits staged by the respective schools would have been a good exhibition of agricultural products for the Halifax Exhibition, even if the rank and file of the farmer exhibitors had not responded as heartily as they did this year. Congratulations to Superintendent DeWolfe.

The prize-winners in the most important sections of the Agricultural Products Class were as follows:—

HORTICULTURAL PRODUCTS

The fruit growers also staged a very good display of their fruits. It is true that at this early date fruit is green and immature, but the visitors can readily understand this condition and will rather judge of the quality of our apples by the freedom from insect and fungus injuries of the varieties staged.

Collection of Pickles—1, Sea View Farm, Mrs. F. J. Porter; 2, Mrs. F. J. Porter.

The Experimental Station, Kentville, Prof. W. S. Blair, Superintendent, staged the most attractive and educational exhibit yet attempted in the Maritime Provinces by any of the Experimental farms. The various models of farm buildings and equipments. The samples of produce and the trite morsels of advice, easily read and easily remembered, conveyed the moral arrived at in no uncertain sound. Visitors, who studied the various features of the display, and who will heed the facts taught, will be well repaid for their visit to the big show.

The prize winners for county fruit collections were:—

Special County Prizes—Fruits

Halifax—1, George Turner, Preston Road; 2, Mrs. Frances J. Turner, Preston Road.

Lunenburg—1, J. W. Hebb, Hebb's Cross; 2, H. T. Hebb, Bridgewater.

Judges:

Harvey Mitchell, Fredericton.

McV. MacKay, Truro.

THE SWINE CLASSES

The swine breeders were not filled very extensively, but there was lots of quality. Pork and pork products have soared to such high prices, that we persume our breeders are not over anxious to take such valuable animals as pigs too far away from home.

J. R. Semple & Son, Truro, N. S.; Alfred Servant, Yarmouth, N. S.; McFarlane Bros.; Chas. Elter and Frank J. Locke, showed some excellent Berkshires. The majority of the first prize winners were from the Semple herd.

There was but a small showing of Yorkshires, with little or no competition in the majority of sections.

J. W. Nicholson and H. W. Corning were the only exhibitors of White Chesters. The choicest plumes going to the Nicholson herd.

J. E. Baker & Sons were the only exhibitors of Duroc Jerseys.

The grade classes were nothing to brag over in point of numbers.

SHEEP

The sheepmen of Prince Edward Island were over with several splendid flocks of outstanding quality. The only Nova Scotia sheep breeders who came forward to help maintain the reputation of their province in sheep-breeding circles were:—John Retson, C. D. Pugsley, McFarlane Bros., Sharp & McNeil, J. E. Baker & Sons and Alfred Servant.

The only walk overs for an exhibitor was in the Hampshire and Cheviot classes, where Cephas Nunn of Prince Edward Island had lots of quality, but no competition.

THE POULTRY

The poultry display was very creditable. Taken as a whole the birds were in good condition and feather. A full list of prize winners is published elsewhere in this issue, where the reader may ascertain who is who as breeders of the respective varieties.

The display of honey and aipiary products was very limited. Chas. Piers of Armdale being the only exhibitor. A province in which the fruit growing industry plays such an important part as apple growing does in Nova Scotia, may well afford to pay more attention to the honey bee.

From every standpoint Nova Scotia's third war time exhibition was most creditable. Sacrifices have been made and must be made, but the work of the agriculturist must not lag. The exhibitors very materially helps to keep the home fires burning and our basis industry advancing until the boys return.

THE HORSES

The showing of horses was not very large, Clydesdales and Standard Breds being the only two classes of which any special mention need be made, so far as numbers is concerned. The reader who peruses the list of awards will readily see that in the other classes competition was very light.

The aged stallion section of the Clydesdale Class, brought out six good sires, a number of them being champions in some of the hottest contests ever waged in Maritime show rings. These were Thorndale by High Honor; Boreland Crest by Scottish Crest; Baron's Own by Baron's Pride; Golden Nugget, Day Dream and Baron Rossiter. The first four stood in the order named, when the judge had placed the ribbons.

Three year old stallions were four in number, viz: Kelvin's Pride; Noble Majestic; Hillside Baron and Scotland Yet.

The best mare, any age, was McFarlane Bros' Nell Bowie by Golden Chief.

Snowball's Baron's Own was first with three of his get. Roper's Thorndale, the first prize aged stallion, was the best imported stallion, while a similar honor for Canadian bred stallion went to Snowball's Kelvin's Pride by Baron Kelvin.

The best Canadian bred mare was Snowball's two-year-old filly, Jenny Lind by Baron's Own.

Seven Standard bred aged stallions faced the judge. Mc Kenarion, Kelly B., Archille and Doctor Cole, were the prize-winners in the order named.

The best brood mare was Harriet King, and her foal by Major Todd led his class.

The diploma for best mare, any age, went to Burton Brenton's Dot Archille.

THE CATTLE

Dairy cattle made a good showing. A. McRae & Sons, McIntyre Bros. and Prescott Blanchard, were out with three exceptionally herds of Ayrshires and competition was keen and close.

McRae's aged bull, Hobsland Tumphie's Heir lead his class, was first with three of his get, headed the first prize aged herd, but did not succeed in winning the championship, an honor which went to his owner's junior yearling, Lochinvar's Champion.

The champion female was McRae's Nellie of Spring Brook Farm, shown in the four year old class.

The leader of the senior yearling bull class was Blanchard's Jean Armour's Lotus, out of the famous Jean Armour. Blanchard also had a magnificent herd of aged and young stock, of which any breeder might well feel proud.

McIntyre Bros' Morton Main's Lady Nelly was the dam of the champion cow and also the dam of the first and second pair of animals progeny of one cow.

The aged herd first prize went to McRae Sons, Blanchard came in for second place. McIntyre Bros. stood down to third position, but came to the fore again by leading with their young herd.

The Jerseys

H. S. Pipes & Son, Cann Bros., J. R. Semple & Sons and J. E. Baker & Sons were out with the best of their Jerseys. Honors were pretty evenly divided between the first two mentioned herds as will be seen by the list of awards. Pipes & Son led with aged and young herds. They also captured the championship prizes on male and female with their aged bull, His Reverence, and their four year old cow, Brampton Mousie.

Cann's aged bull Figgis Fox's Gem Fox was first with three of his get, who was also the sire of the best four animals get of one sire.

Guernseys

were shown by Pipes Bros. and H. W. Corning. Both herds were in fine fettle and the individuals were brimming over with quality. The Corning herd comprises some of the sweetest and trimmest young Guernseys we have seen for many days. Many of these are the get of Island Prince of Hillside, the aged bull at the head of the herd, and the champion of this and many previous shows.

The champion female was Corning's champion, Dairymaid of Hillside, shown in the aged cow class. Her progeny has put the Corning herd on the map. The majority of the individuals in the Corning show herd are the daughters, and in some cases the daughters and grand-daughters of Island Prince of Hillside, a line of breeding that gives exceptionally good results.

Holsteins

Harding Bros. and S. Dickie & Son were the principal exhibitors of Holsteins. Look up the list of awards and see where the respective herds and individuals were placed. The male championship went to the New Brunswick herd of their aged bull, Sir Foforit Schuling by Schuling Sir Posch out of Foforit 7th Beauty. The Nova Scotia herd captured the female championship with Maggie Abbekerk, first prize winner in the dry four-year-old class.

Harding's champion bull was first with three of his get, and their Foforit 7th Beauty, champion at Quebec, and second in class of 28 at Sherbrooke, was first with two of her progeny.

Both herds were out in fine shape, and a credit to their breed.

Shorthorns

J. M. Laird & Son of Prince Edward Island, R. A. Snowball of New Brunswick and A. N. Griffin of Nova Scotia put up a three cornered contest with a trio of well fitted Shorthorn herds. The champion bull was Laird's aged bull, Stately Monarch, a former sire in the Griffin herd that left his good marks in the splendid individual prize winners shown by Mr. Griffin. The champion female was Laird's Stately Blossom, a senior yearling calf.

Aberdeen Angus

Horne Bros. of Prince Edward Island, A. G. Spafford of Quebec and Geo. A. Black of New Brunswick were on hand with some good doddies. The male championship went to the youngest exhibitor, Mr. Black on h,s senior yearling, Buster Winsloe.

The champion female was Spaffords Junita. Horne Bros. led the way

with young herd, while Spafford led in the aged bull class.

Herefords and Devons

Wm. O'Brien & Sons had everything their own way with their Herefords, and Wm. A. Pinkney had a similar walkover with his Devons.

PRIZE WINNERS AT HALIFAX EXHIBITION

HORSES

General Purfose

Mare or Gelding, 4 years old—1, Wm. Robinson, Halifax; 2, Wm. McMann, Truro. 3, Frank Archibald, Truro.

Mare or Gelding, 3 years old—1, Geo. M. Holmes, Amherst; 2, S. D. Kerr, Milford Sta.

Brood Mare with Foal—1, Clifford S. Tanner, Halifax.

Foal of 1917—1, Clifford S. Tanner.

Matched Team—1, S. D. Kerr.

Light Draught or Agricultural Horses

Mare or Gelding, 4 years old—1, Sharp & McNeil, Windsor.

Mare or Gelding, 3 years old—1, Sharp & McNeil.

Filly or Gelding, 2 years old—1, Geo. M. Holmes.

Filly or Gelding, 1 year old—1, McFarlane Bros., Fox Harbour Pt., N. S.; 2, Geo. M. Holmes.

Matched Team—1, Geo. M. Holmes.

Heavy Draught Horses

Mare or Gelding, 4 years old—1, S. D. Kerr; 2, Sharp & McNeil.

Filly or Gelding, 1 year old—1, Sharp & McNeil.

Matched Team—1, McFarlane Bros.

Coach Horses

Stallion, 4 years old—1, H. C. Jewett, Fredericton.

Clydesdales

Stallion, 4 years old—1, Roper Bros.; 2, McFarlane Bros.; 3, R. A. Snowball, Chatham, N. B.; 4, Sharp & McNeil; 5, C. A. Stevenson, New Glasgow.

Stallion, 3 years old—1, R. A. Snowball; 2, H. C. Jewett, Fredericton; 3, Prescott Blanchard; 4, H. C. Jewett.

Stallion, 2 years old—1, H. Purdy & Sons, Wentworth Station, N. S.; 2, A. W. Nelson, Hartford, N. S.; 3, McFarlane Bros.

Stallion, 1 year old—1, Prescott Blanchard, Truro.

Brood Mare with Foal—1, Prescott Blanchard; 2, Prescott Blanchard.

Filly, 4 years old—1, McFarlane Bros.; 2, R. A. Snowball; 3, McFarlane Bros.

Filly, 3 years old—1, McFarlane Bros.; 2, McFarlane Bros.

Filly, 2 years old—1, R. A. Snowball; 2, Geo. M. Holmes; 3, McFarlane Bros.

Filly, 1 year old—1, R. A. Snowball; 2, McFarlane Bros.; 3, R. A. Snowball.

Foal of 1917—1, Prescott Blanchard; 2, Prescott Blanchard.

Stallion, and 3 of his get—1, R. A. Snowball.

Mare, any age—1, McFarlane Bros.

Clydesdale Association Specials

Best Imported Clydesdale Stallion—1, Roper Bros.; 2, McFarlane Bros.

Best Imported Clydesdale Females—1, McFarlane Bros.

Best Canadian Bred Stallion—1, R. A. Snowball.

Best Canadian Bred Female—1, R. A. Snowball.

Best Single Mare or Gelding in Harness—1, McFarlane Bros.

Best Matched Team in Harness—1, Sharp & McNeil; 2, McFarlane Bros.

Best Stallion, any age—1, Roper Bros.

Percherons

Stallion, 4 years old—1, H. C. Jewett, Fredericton.

Filly, 3 years old—1, Wm. McMann, Truro.

D. J. Grey, Bryonville, Ont., Judge.

Thoroughbreds

Stallion, 3 years old—1, Geo. M. Holmes.

Brood Mare with Foal—1, Geo. M. Holmes.

Filly, 4 years old—1, Geo. M. Holmes.

Filly, 1 year old—1, Geo. M. Holmes.

Foal of 1917—1, Geo. M. Holmes.

Standard Breds

Stallion, 4 years old—1, Wm. McManus, Truro; 2, Blanchard Brenton, Brentwood, N. S.; 3, Albert Harty, Lower Stewiacke, N. S.; 4, Clifford W. Whalen, New Germany, N. S.

Stallion, 3 years old—1, Ines & Murdock, Montague, P. E. I.

Stallion, 2 years old—1, P. G. McDonald, Upper Dyke Village, N. S.; 2, W. H. Muir, Halifax; 3, C. A. Musgrave, Halifax.

Stallion, 1 year old—1, P. G. McDonald; 2, Dr. G. A. Polley, Lunenburg.

Brood Mare with Foal—T. C. Latham, Alma; 2, C. A. Musgrave.

Filly, 4 years old—1, Geo. M. Holmes; 2, L. R. Acker, Halifax; 3, R. E. Feltus, Lawrencetown.

Filly, 2 years old—1, Burton Brenton, Truro; 2, H. S. Pipes & Son.

Filly, 1 year old—1, H. S. Pipes & Son.

Foal of 1917—1, T. C. Latham; 2, Wm. McManus; 3, C. A. Musgrove.

Stallion, any age—1, Wm. McManus.

Brood Mare, any age—1, Burton Brenton.

Roadsters

Brood Mare with Foal—1, S. D. Kerr; 2, Dr. C. A. Hawkins, Halifax; 3, Geo. M. Holmes.

Filly or Gelding, 3 years old—1, Geo. M. Holmes; 2, John E. Goodwin, Halifax; 3, Aubrey A. Whitman, Torbrook, N. S.

Filly or Gelding, 2 years old—1, Geo. M. Holmes.

Filly or Gelding, 1 year old—1, Geo. M. Holmes; 2, Merriel Newcombe, Halifax.

Foal of 1917—1, S. D. Kerr; 2, Dr. C. A. Hawkins; 3, Mrs. C. M. Hart, Antigonish.

Matched Pair—1, Horne Bros., Winsloe Sta., P. E. I.; 2, Geo. M. Holmes.

Single Horse in Harness—1, T. C. Latham; 2, Thos. Buckley, Sydney, N. S.; 3, H. C. Lydiard, Centreville, N. S.; 4, Horne Bros.; 5, Frank Gardener, Stewiacke.

Carriage Horses

Brood Mare with foal—1, S. H. James, Halifax.

Filly or Gelding, 3 years old—1, R. A. Snowball; 2, Geo. M. Holmes; 3, S. H. James.

Filly or Gelding, 1 year old—1, Geo. M. Holmes.

Foal of 1917—1, S. H. James.

Pair Matched—1, R. A. Snowball; 2, Geo. M. Holmes; 3, Otis Gardener, Shubenacadie, N. S.

Single Horse in Harness—1, R. A. Snowball; 2, Geo. M. Holmes; 3, Otis Gardener.

Ponies

Stallion, over 12 and under 14 hands—1, R. A. Snowball; 2, John D. McLellan, Halifax.

Mare or Gelding, over 13 and under 14½ hands—1, Wm. Robinson, Halifax; 2, John D. McLellan, Halifax.

Mare or Gelding, over 12 and not over 13 hands—1, Blanchard Brenton; 2, John D. McLellan.

Mare or Gelding, under 12 hands—1, A. D. Johnson, Halifax.

Shetland Stallion, not over 10½ hands—1, Miss Elizabeth Freeman, Halifax; 2, C. P. Spencer, Truro.

Shetland Mare or Gelding, not over 10½ hands—1, C. P. Spencer; 2, C. P. Spencer.

Hackney Horses

Stallion, 4 years old—1, R. A. Snowball.

Filly, 4 years old—1, Geo. M. Holmes.

Filly, 1 year old—1, R. A. Snowball.

Best Stallion (Hackney Society Silver Medal)—1, R. A. Snowball.

Best Mare, (Hackney Society Silver Medal)—1, R. A. Snowball.

Saddle Horses

Horse ridden by gentlemen—1, Horne Bros.; 2, Wm. Robinson.

Horse ridden by lady—1, Miss O'Brien; 2, Geo. M. Holmes; 3, Wm. Robinson.

Tandems

Mares or Geldings, over 14.2 hands, shown to suitable vehicle—1, R. A. Snowball; 2, Horne Bros.; 3, Geo. M. Holmes.

DAIRY CATTLE

Ayrshires

Bull, 3 years old—1, A. McRae & Sons, Charlottetown, P. E. I.; 2, McIntyre Bros., Sussex, N. B.

Bull, senior yearling—1, Prescott Blanchard, Truro, N. S.; 2, McIntyre Bros.

Bull, junior yearling—1, A. McRae & Sons; 2, McIntyre Bros.; 2, John Retson, Truro.

Bull Calf—1, McIntyre Bros.; 2, Prescott Blanchard; 3, McIntyre Bros.; 4, Prescott Blanchard.

Cow, dry, 4 years old—1, Prescott Blanchard; 2, A. McRae & Sons; 3, McIntyre Bros.; 4, John Retson.

Cow, 4 years old—1, A. McRae & Sons; 2, A. McRae & Sons; 3, McIntyre Bros.; 4, McIntyre Bros.

Cow, 3 years old—1, Prescott Blanchard; 2, A. McRae & Sons; 3, McIntyre Bros.; 4, Prescott Blanchard.

Heifer, 2 years old—1, John Retson; 2, A. McRae & Sons; 3, A. McRae & Sons; 4, Prescott Blanchard.

Heifer, senior yearling—1, McIntyre Bros.; 2, Prescott Blanchard; 3, A. McRae & Sons; 4, Prescott Blanchard.

Heifer, junior yearling—1, McIntyre Bros.; 2, McIntyre Bros.

Heifer Calf—1, A. McRae & Sons; 2, McIntyre Bros.; 3, McIntyre Bros.; 4, McIntyre Bros.; 5, John Retson.

Bull and 3 of his get—1, A McRae & Sons; 2, McIntyre Bros.

Cow and 2 of her offspring—1, McIntyre Bros.; 2, A. McRae & Sons.

Aged Herd—1, A. McRae & Sons; 2, Prescott Blanchard; 3, McIntyre Bros.

Breeder's Young Herd—1, McIntyre Bros.; 2, A. McRae & Sons; 3, McIntyre Bros.

Champion Female—A. McRae & Sons.

Champion Male—1, A. McRae & Sons.

Four Animals, get of one sire—1, A. McRae & Sons; 2, Prescott Blanchard; 3, McIntyre Bros.

Two Animals, progeny of one cow—1, McIntyre Bros.; 2, McIntyre Bros.; 3, A. McRae & Sons.

Jerseys

Bull, 3 years old—1, H. S. Pipes & Son, Amherst, N. S.; 2, Cann Bros., Chegoggin, N. S.; 3, H. S. Pipes & Son.

Bull, 2 years old—1, H. S. Pipes & Son.

Bull, senior yearling—1, J. R. Semple & Son, Truro; 2, H. S. Pipes & Son; 3, J. E. Baker & Sons, River Hebert, N. S.

Bull, junior yearling—1, Cann Bros.

Bull Calf—1, Cann Bros; 2, J. R. Semple & Son; 3, H. S. Pipes & Son.

Cow, dry, 4 years old—1, Cann Bros.; 2, Cann Bros.; 3, H. S. Pipes & Son.

Cow, 4 years old—1, H. S. Pipes & Son; 2, H. S. Pipes & Son; 3, Cann Bros.

Cow, 3 years old—1, Cann Bros.; 2, H. S. Pipes & Son; 3, J. R. Semple & Son.

Heifer, 2 years old—1 and 2, Cann Bros.; 3, H. S. Pipes & Son.

Heifer, senior yearling—1, H. S. Pipes & Son; 2, Cann Bros.; 3, H. S. Pipes & Son.

Heifer, junior yearling—1, H. S. Pipes & Son; 2, Cann Bros.; 3, H. S. Pipes & Son.

Heifer Calf—1, Cann Bros.; 2, H. S. Pipes & Son; 3, J. R. Semple & Son.

Bull, and 3 of his get—1, Cann Bros.

Female and 2 of her offspring—1, H. S. Pipes & Son.

Aged Herd—1, H. S. Pipes & Son; 2, Cann Bros.

Breeders' Young Herd—1 and 3, H. S. Pipes & Son; 2, Cann Bros.

Champion Bull—1, H. S. Pipes & Son.

WHAT MAY BE EXPECTED OF AN EFFICENT COMMUNITY ORGANIZATION

The result of any legitmate effort for uplife in any particular community, will depend upon the men in that area. No one man can do the necessary work. It must be done through the combined interest and efforts of the men who are either directly or indirectly interested in a particular movement.

The president and officers cannot do all the work, and they should not be expected to do it. The problem is usually one for the entire community. What is one man's interest is every man's interest. Vigilance, promptness and concerted action on the part of everyone will spell success. In working out the details of organization, many questions will come up for settlement. Most of these will have to be left to the executive board. The countless details can in this way be threshed out without calling the general membership together. Much will depend upon the officers in the organization. They must be men in whom the community has confidence, and men who will take a broad, public-spirited view of matters. If a community can secure the right sort of men to handle the work in the organization, and the individual members will each feel a personal responsibility for the conditions and results, much can be accomplished for the community. Such an organization will create an interest in the business, reduce the loss, consequently lower the cost of production, and increase both the pleasure and profits from the business.

THE LATE C. W. McDOUGALL

The dairy industry of New Brunswick has sustained a severe loss in the death of its Superintendent, Mr. C. W. McDougall, which occurred at his home, Sussex, on Tuesday evening, September 11th.

His family and friends were shocked when on Thursday morning, September 6th, it became known that he had been run over by an automobile, and that his condition was serious. Hopes brightened when the doctors were able to perform an operation on Saturday, that seemed successful. The skull was, however, so badly fractured and the body so badly bruised, that complications set in, and he finally passed away.

The late Mr. McDougall was well known in dairy circles, and had a host of friends all over Canada. To know Mr. McDougall was to respect him. He did his work conscientiously and without fear or favor, and always upheld a square deal to everybody.

He is gone. We knew him intimately for over ten years. We will miss him. We know we voice the sentiments of all who knew him, when we say that our deepest sympathy goes forth to his sorrowing wife and little children, Jean, Ruth, and Robert, to whom he had been an ideal husband and father.

SAVING BY PLANNING

The man who first announced that the food necessity of the world bound upon every person the obligation to save, but not to hoard, scored a total success. The dictionary was against him, but the mental state of the world was favorable. According to the dictionary, saving is hoarding and hoarding is saving. But as the word has one into all the world, the best thing to do in the circumstance is stop chasing it and turn our attention to the business of getting along as well as we can. The duty of saving is no more binding now than it always has been, for we do not understand that any new moral law has been created since the commencement of the great war. There is no good reason why the people should not continue to eat and dress normally, which would be according to the moral law. Shifts and adjustments will have to be made, no doubt, but they should be made calmly and prudently.

Planning is the word that should have been sent out, a planning that will reduce the cost of necessities but not their real value as food or dress or utility. The present emergency may sanction the plan of giving up wheat bread on certain days or at certain meals, but wholesome corn bread or oaten loaf is substituted. The body requirements will be supplied, and at the same time a proper adjustment will have been effected. The dishes will be changed, but the nourishing value of the food will be the same.

BUSINESS FARMING

According to a newspaper report which may not be far out of the way, the world's record for large acreage has been beaten up in Alberta by an American named C. S. Noble. Just recently his last load of grain hauled by a team of prize Clydesdales, drew up at the elevator at Lethbridge completing o total of 54,383 bushels from 1,000 acres of land. Behind it was a procession of autos filled with members of the local board of trade.

It is not many years since Noble left the United States to make a modest start in Canada. Now he owns three farms, and it is said his 1916 crop netted him $100,000.

The history of this record crop shows that the most modern business methods were used in its production. The work required 120 men, and these were directed by telephone from a central office. When Mr. Noble's presence was required at any place, a high powered automobile whirled him there in quick time.

Now we are not holding this up as an instance of what can be done by most anybody following business methods, etc., because "anybody" can't do it. Farming on such a scale as this is the privilege of relatively few. But it would hot have been possible at all unless a well-planned system had been followed to the letter; and now, the crop harvested and marketed, the books are being balanced from entries made according to such a cost system as is used by any great factory. But it is possible for any farmer to so plan his work as to make it come out to the best advantage at the end of the year. Part of his plan would naturally include a well-kept record, showing what his costs of production had been, so that he could compare them with the income from it. Not the least use of such a record is that it shows pretty closely what department of farm operation has paid most and what has paid least, if at all; and the natural suggestions that would come to the farmer who has kept such a record, will be of ample value to recompense hi mfor all the truble he has taken.

Farming is a business, just the same as any other occupation is. The farm is a factory. The fact that a great many farms and some factories are operated with apparent success without reference to some business system proves nothing, except that they would have been wonderfully successful had they been conducted according to a definite plan.

MOBILIZE FARM LABOR

Our country is facing the greatest crisis in her history. Not only are we actually at war with the greatest military power which is also next to the greatest naval power in the world, but we are facing a food situation that is giving the greatest concern to thinking people.

This country needs its young men in its training camps, making ready as speedily as possible for the work, whether offensive or defensive, they may be called upon to do. This is the country's greatest need; and the need is urgent; for we shall be fortunate if we can at least hold the advantages we have won until other forces are made ready.

But hardly less important is the work left for those remaining at home, whatever their age or disqualifications for military service, to do. For it is the accepted truth that the winning or losing of this war may lie with the farmer.

The main factor in the production of a bountgous harvest is the labor necessary for it. It is that our agricultural yield can be doubled—on conditon that we supply enough labor.

It is the labor buestion that is vital. And while the young manhood of the nation is at the front ready to sacrifice even their lives for the Nation's good, it is meet that those who are left behind should let no sacrifice stand ni the way of assuring the food supply of the Nation for the next year to come, at least. The young fellows under the legal age of enlistment can serve their country almost equally as well by enlisting in the farm brigade; for it is a certainty that mobilization of labor forces for increasing the food supply will come just as surely as mibilization of our fighting forces. The boy too young to enlist can quickly learn to handle any farm implement as well as his elders and become a fighting unit accordingly. And his services are regarded as highly important by those who are forwarding this mobilization plan.

And to every man who does not actually take up arms for his country we urge the necessity of his being on the farm and working as he never worked before.

The Charlotte County Exhibition

The 1917 fall fairs season has again arrived. Charlotte county led the way by throwing its gates open to the public on November 11th to 14th.

Secretary Stevens and the various officials who have the oversight of this important county fair, worked hard during the early spring and all through the season to induce the agriculturists of Charlotte county to do their utmost, not only to increase production but also to plan to show some of the fruits of their labors at the fair. The outlook was discouraging at times, owing to the fact that weather conditions and scarcity of farm labor greatly handicapped the work of the farmers, many of whom could scarcely see their way clear to spend much time on exhibition matters. However, the fact that the Department of Agriculture was ready and willing to grant seventy-five per cent. of the amounts paid out in prize money, induced many of the farmers to undertake some self-sacrifice in the way of extra work, so that good old Charlotte county would not be weighed in the balance and found wanting in a display of agricultural products.

The display of Live Stock, although not very large, was quite creditable. No special effort had been put forth to fit the cattle for the show. They were just an average lot of cattle kept under ordinary farm conditions in field fit. The pure bred classes included Jerseys, Ayrshires, Canadians and Holsteins. The special prize—a silver cup—donated by the St. Croix Courier, for the best bull, any breed, was captured by a two-year-old Ayrshire, shown by W. T. Reid, Rollingdam.

This cup was won in 1916 by Mr. Edwell Smmerson. E. O. McIntyre, Sussex, placed the awards.

The horses were judged by J. F. Frost, Hampton. There were several very nice horses in the ring, particularly in the Standard Bred, carriage, Farm Work and Heavy Draught Classes. LaForest Robinson showed a nice Clydesdale stallion by Sorbie Boy.

Thos. Hetherington, the Live Stock Superintendent for the province judged the Sheep and Swine, and gave universal satisfaction. There were some very nice sheep in the pens. Judging by the conversation heard at the ringside, Charlotte County farmers are greatly interested in the sheep industry.

The Swine classes were not large. Yorkshires, Berkshires and Tamworths were the pure breeds represented. The most outstanding individual in the pens was an eight months old barrow, shown by Mr. Thos. McDonald, St. Stephen. Mr. McDonald can grow pigs to perfection. In 1915 his pair of exhibition pigs dressed 900 pounds. His 19'6 pair dressed 896 pounds and the Yorkshire-Chester Cross barrow shown by him this year will step up pretty close to fifty per cent. of either set of figures.

The splendid display of field and garden roots, vegetables and grain was judged by Messrs. Wm. Kerr and O. C. Hicks. Considering the character of the past season, Charlotte County soil gave a good account of its stewardship. Charlotte County is becoming a strong horticultural county and many of the popular varieties grow there to a very creditable degree of perfection. Messrs. W. B. Gilman and W. P. Fox placed the awards. These gentlemen are both practical fruit growers and well qualified to give their fellow fruit growers some valuable ideas on the problems confronting them.

The schools of St. Stephen and Moore's Mills made good displays of the crops grown in their gardens.

The poultry display was judged by Seth Jones, in his usual painstaking manner. The display included a nice lot exhibited by members of the York County Poultry Keepers AssoAciation. H. M. McMonagle of Fredericton was there with a nice string of birds that were good enough to capture some of the choicest laurels at Sherbrooke.

Mr. Harvey Mitchell judged the dairy products display—a very creditable little show.

L. T. Floyd, the Aipiary judge, was kept busy for a while in placing the bee products. Many farmers in Charlotte County are interested in bees, and no where could they find one more interested in their work than Mr. Floyd, who as a practical bee man is now employed by the provincial department of agriculture to foster the industry.

The domestic and ladies' work departments were well filled and reflected much credit on the good housekeepers and home-makers of Charlotte County. Among the fancy work exhibits was some embroidered work, over one hundred years old, that attracted much attention.

The exhibition was well patronized. On Wednesday turnstiles registered close to 10,000 paid admissions, a record attendance. The attendance on the other days was also large, and every one seemed to enjoy the display in the various departments, the tented-city shows and the races, but perhaps the most interesting feature that attracted many of the visitors was a series of trenches and battle-front equipment, dug and looked after by returned soldiers. The visitors who walked through the zig-zagged trenches, dugouts, hospitals, machine gun apartments and steered clear of the wire fence entanglements, on which effices of dead German soldiers were hung and listened to the careful explanations of their soldier guides, can better understand what they read about matters of this kind.

The fair was a decided success and well warrants the 75% of prize awards paid by the Department of Agriculture.

HORSES

Standard Bred.

Stallion, 4 years old—1, Wilfred Todd, Milltown.

Stallion, 1 year old—1, Jas. McAllister, Milltown.

Filly or Gelding, 4 years old—1, W. F. McGibbon, Moore's Mills; 2, B. J. Maxwell, St. Stephen.

Filly or Gelding, 3 years old—1, Mrs. Arthur H. White, Moore's Mills; 2, W. F. McGibbon.

Filly or Gelding, 2 years old—1, W. F. McGibbon.

Carriage Horses to Halter

Filly or Gelding, 4 years old—1, David Johnson, St. Stephen; 2, Hugh Love, St. Stephen; 3, W. R. Simpson, Oak Bay.

Filly or Gelding, 3 years old—1, D. R. Chowen, Oak Hill; 2, Walter DeWolfe, St. Stephen; 3, Frank Clark, Sr., Moores' Mills.

Filly or Gelding, 2 years old—1, Ralph Stewart, St. Stephen; 2, D. R. Chowen, Oak Hill.

Carriage Horses to Harness

Stallion, 4 years old—1, E. F. Corbett, Milltown.

Mare or Gelding—1, Theo. Murchie, St. Stephen; 2, Robert Webber, Milltown; 3, Elwell DeWolfe, St. Stephen.

Matched Team—2, D. R. Chowen; 3, W. F. McGibbon.

Farm or Work Team

Brood Mare with Foal—1, J. A. Goudy, Waweig.

Mare or Gelding, 4 years old—1, Geo. H. Budd, St. Stephen; 2, Melbourne Reynolds, St. Stephen; 3, Harrison Pomeroy, Little Ridge.

Filly, 3 years old—1, Geo. Trafton, St. Stephen.

Filly, 2 years old—1, S. I. Irving Moores' Mills.

Filly or Gelding, 1 year old—1, J. A. Goudey.

Foal of 1917—1, Geo. H. Budd; 2, Harrison Pomeroy; 3, Pollys Forsythe.

Heavy Draft Horses

Mare or Gelding, 4 years old—1 and 2, David Johnson.

Filly or Gelding, 3 years old—1, W. E. Moffitt, St. Stephen.

Matched Team

1, David Johnson.

Clydesdales

Best Stallion, any age—1, La Forest Robinson, St. Stephen.

French Canadian

Stallion, any age—1, Harry Acheson, Elmsville.

CATTLE

Class 14—Jerseys

Bull, 2 years old—1, Jas. A. Maxwell, St. Stephen.

Bull, Junior—1, Polleys Forsythe; 2, Wilfred Todd.

Cow, 4 years old or upwards—1, Thos. McClure; 2, Jas. A. Maxwell.

Heifer Calf, 6 months old and under—1, Jos. Thomas, St. Stephen.

Class 15—Ayrshires

Bull, 2 years old—1, A. T. Reid, Rollingdam.

Bull, senior yearling—1, Cameron Berry, Oak Bay.

Bull Calf—1, Walter Howland; 2, Wilfred Todd.

Cow, 4 years old or upwards—1 and 2, A. T. Reid; 3, H. Freeman Lever.

Cow, 3 years old—1, A. T. Reid.

Cow, 2 years old—1, Walter Howland.

Heifer, 2 years—1, H. Freeman Lever; 2nd. A. T. Reid.

Heifer, senior—1, Martin Reid.

Heifer, junior—1, A. T. Reid.

Heifer Calf over 6 months, under 1 year—1, Martin Reid, Leverville; 2, Wilfred Todd.

Heifer Calf, 6 months old and under—1, A. T. Reid.

Herd Bull and 4 females—1, A. T. Reid.

Class 16—Holsteins

Holstein Bull, 2 years—1, Clarence Maxwell, St. Stephen.

Bull, senior—1, D. Hyslop, St. Stephen.

Bull, junior—1, Manzer Moffitt, St. Stephen.

Bull Calf, over 6 months, under 1 year—1, Albion Moffitt.

Bull Calf, 6 months and under—1, Manzer Moffitt.

Cow, 4 years and upwards—1, Hardy Barter, St. Stephen; 2, Albion Moffitt; 3, Manzer Moffitt.

Cow, 3 years old—1, W. E. Moffitt, St. Stephen.

Cow, 2 years old—1, Manzer Moffitt.

Heifer, senior—1, Albion Moffitt.

Herd, 1 Bull, 4 females—Manzer Moffitt.

Class 17—French Canadian

Bull, senior—1, W. S. Poole, St. Stephen.

Bull Calf, 6 months and under—1, Manzer Moffitt.

Cow, 4 years or upwards—1 and 2, W. S. Poole; 3, Manzer Moffitt.

Cow, 3 years old—1, W. S. Poole.

Cows, 2 years old—1, W. S. Poole.

Heifer Calf, 6 months and under—1, W. S. Poole.

Herd Bull and 4 females—1, W. S. Poole.

Class 18—Any other Pure Breeds of Dairy Cattle

Cows, 2 years old (Guernsey)—1, W. R. Simpson, Oak Bay.

Class 19—Beef Grades

Cow, 3 years or upwards—1, Manzer Moffitt.

Heifer, 2 years and under 3 years—1, W. E. Moffitt.

Heifer, 1 year and under 2 years—1, W. E. Moffitt; 2, Albion Moffitt.

Heifer Calf, under 1 year old—1 Manzer Moffitt.

Steer, 2 years old and under 3 years—1, W. E. Moffitt.

Steer, 1 year old, under 2 years—1, W. E. Moffitt.

Steer Calf, under 1 year—1, W. S. Stevens, St. Stephen; 2, W. E. Moffitt; 3, Manzer Moffitt.

Herd Bull and 4 females—1, W. E. Moffitt.

Class 20—Grade Jersey

Cow, 4 years old or upwards—1 and 2, Polleys Forsythe; 3, Hazen Linton, St. Stephen.

Cow, 3 years old—1, Polleys Forsythe.

Cow, 2 years old—1, Jas. Manuel, Mohanas; 2, Polleys Forsythe; 3, Chas. Middlemist.

Heifer, 2 years old—1, W. E. Moffitt; 2, Frank Clark, Sr., Moores' Mills.

Heifer, 1 year old—1, Polleys Forsythe; 2, Wellington Thompson, Dufferin; 3, Melbourne Reynolds, St. Stephen.

Heifer Calf, 1 year and over 6 months—1, Kenneth Maxwell, Bay Road; 2, Wm. Moffitt.

Heifer Calf, 6 months or under—1 and 2—Polleys Forsythe; 3, H. D. McKay, St. Stephen.

Herd Bull and 4 females—1, Polleys Forsythe; 2, Wm. Moffitt.

Cow and 3 of her progeny—1, Polleys Forsythe.

Class 21—Grade Ayrshire

Cow, 3 years old—1, Martin Reid.

Heifer, 1 year old—1, A. T. Reid; 2, Ray Lever, Leverville; 3, H. Freeman Lever.

Heifer Calf, 1 year and over 6 months—1, Ray Lever.

Heifer Calf, 6 months old and under—1, A. T. Reid; 2, Martin Reid; 3, Wm. Moffitt.

Grade Holsteins

Cow, 4 years and upwards—1, Wellington Thompson; 2, Albion Moffitt; 3, Manzer Moffitt.

Cow, 3 years—1, Albion Moffitt; 2, Melbourne Reynolds; 3, W. M. Moffitt.

Cow, 2 years old—1, Ralph Stewart, St. Stephen; 2, Harry Reynolds, St. Stephen; 3, Melbourne Reynolds.

Heifer, 2 years old—1, Fred Coffee, St. David; 2, Wm. Moffitt; 3, Seth Bartlett.

Heifer, 1 year old—1, Ralph Stewart; 2, Albion Moffitt; 3, Wilfred Todd.

Heifer Calf, 1 year and over 6 months—1, Howard Dinsmore, St. Stephen; 2, Wm. Moffitt, St. Stephen.

Heifer Calf, 6 months old or under—1, Harry Reynolds; 2, Albion Moffitt; 3, Joseph Thomas.

Herd Bull and 4 females—1, Albion Moffitt; 2, Wm. Moffitt.

Class 23—Grade French Canadian

Cow, 4 years or upwards—1, L. B. Mitchell, St. Stephen; 2, Richard Thomas, St. Stephen.

Cow, 2 years old—1, Edward Hanson, St. Stephen.

Heifer, 1 year old—1, Thomas Bartlett, Old Ridge.

Heifer Calf, 1 year, over 6 months—1, Wm. Moffitt.

Heifer Calf, 6 months old or under—1, Hazen Linton; 2, W. S. Poole; 3, Wm. Moffitt.

Class 24—Other Grade Dairy

Cow, 4 years—1, Wm. Moffitt.

Class 25—Fat Cattle, Any Breed or Grade

Best Beef Animal, not over 2 years—1, Frank Clark, Sr.; 2, Wm. Moffitt.

Pair Fat Cattle, any age—1, Jas. McAllister, Milltown.

Specials

British North American Prize.

Make your FENCEPOSTS ROT-PROOF

DID you know that the ordinarily good fence post which you are accustomed to replacing every four or five years could be made to last 20 years? Creosote treatment does it. And Grade-One Liquid Creosote Oil brings this advantage right to your door because it is creosote in such form that the average home owner and farmer can use it.

Barrett's Grade One LIQUID Creosote Oil

The biggest point about Creosote Oil is that you can apply it by brushing or dipping. No cumbersome, closed-cylinder method. Just as simple as painting. And it penetrates deeper than any other preservative. Stop those costly renewals. Use this wonderful preservative on all wood work exposed to earth or dampness.

FOR SUMMER WEAR

POSTPAID TO YOU FOR

$4.50

The wonderful chromoil leather in these boots is a big improvement on the best ordinary "Oil-Tan." It is waterproof not only on the surface but all the way through. It does not dry out nor crack from heat, nor stiffen up quickly from frost. It retains through everything the soft suppleness that makes it so comfortable.

The shape, too, is new and better, combining the easy comfort of the Indian moccasin with the permanent form of a regular boot. This is ensured by building it on a last, and giving it a solid extra long counter in the heel. It's a boot that will stand up to the hardest kind of service, in any weather, and outwear any other working boot you have ever tried.

At the same time, it is light in weight and easy on the feet, and remarkable value for the price.

If your dealer cannot supply you with these new Palmer-McLellan Chromoil Tanned Farm Boots, mail us the price and we will ship you a pair postpaid.

Men's	Sizes	6 inches high,	per pair $4.50

HORTICULTURE

DRIED FRUITS

Sugar is one of the most remarkable preservatives known and when fruits are dried the natural sugar in them will prevent decay if all the moisture is evaporated and they are kept in a dry place.

Apricots, peaches, apples, even pears and small fruits are now evaporated and offer one solution for saving fruits where there is a lack of cans or jars. Hot sunshine or a patent evaporator is needed for this method and even our government experts who seem to think anything possible for our women to accomplish, admit that sun drying of fruits, aside from apples and pears is scarcely practicable for the home woman.

But the use of dried fruit is a good way to supply the body with many necessary elements of diet through the winter, moreover one pound of dried fruit is equivalent to four pounds of fresh fruit when it is properly cooked so the economy is well worth while.

If you want to try your hand at fruit drying spread the freshly picked fruit on a clean strip of muslin and cover it with netting, then set it in the hot sunshine. The fruit must be turned often so that it will dry evenly and the fruit must be put out in the sun daily until well dried.

If you wish to utilize the heat that rises from the kitchen stove for drying, or if a wet bit of weather comes before the outdoor process is completed, you can swing a home made drier from the kitchen ceiling so it will hang over the range or it may be made to fit into the oven.

All vegetables and fruits must first be blanched before being dried. To blanch small fruit put them in a wire basket or cheese cloth bag and plunge it into boiling water. Drain well and put to drying and see that no dew, drain or steam wets the food.

To make a drier that will last several seasons and may be used in the oven, out of doors or over tht stove, take a strip of galvanized, not brass nor painted netting and tack to a frame made of lath or strips of wood. Another framed netting may be made to fit over this if you like.

Cooked fruits require less sugar than fresh fruits to sweeten them and sometimes the fruit is to be used in puddings or in some similar way and a very sweet fruit is not needed, so canning without sugar is a sensible method.

If it is not convenient to make your jellies now on account of the cost of sugar and the scarcity of containers save the fruit juices, boil them down one half, bottle them and next winter make the jelly as you need it. The fruit juices keep splendidly and the jelly is quite as good as though made now. Pudding and cake sauces may be made from the fruit juices also and since we are not canning water this season but condensing our canned stuff so each jar is well filled with solids you may be glad to have the rich, boiled fruit juice to add to your pies or table fruit.

GIVING THE BEES ROOM

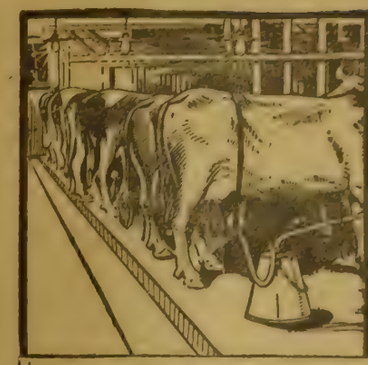
Many beekeepers make a serious mistake in failing to give their bees enough storage room on time. The addition of this room at just the right time for the storage of the season's crop of honey requires good judgment and an intimate knowledge of the nectar resources of the particular locality and season. Very few people realize that in many localities the entire season's crop of surplus honey is gathered and stored within a period of a few weeks. It is exceedingly important during these few weeks that the progress of the work in the supers be watched closely and additional room be given as rapidly as the bees can use it.

The usual procedure by the inexperienced beekeeper is to put on a super of 25 to 50 lbs. capacity during early spring and give the subject no further thought until late summer or autumn. If the super is found to be full of honey at that time, it is removed and probably an empty one put in its place. In many cases this empty super is given long after there is any possibility of any further storage of honey during the season and if comb-honey is being produced the sections and foundation are ruined for further use by being on the hives during a time when no honey is being stored.

During a poor season a single super for each colony may furnish an abundance of room for the storage of the entire crop of hney but, during a good season, if additional supers are not given as needed, the major portion of the crop is lost to the beekeeper simply from lack of storage space.

In comb-honey production, the standard supers contain when filled only about 25 lbs. of honey. During a rapid honey flow such as occurs some seasons, sufficient progress is frequently made in each newly added super to justify the addition of another, every three or four days. With such a honey flow several supers may be completely filled with honey before any of it is ripened and sealed and the hive may have therefore as many as 5 or 6 supers at one time. Under such conditions, if the bees are compelled to ripen and seal the honey in the first super before a second one is given, most of the possible honey crop is lost to the beekeeper, the bees being compelled either to swarm or to loaf during the height of the storing season. Such an abundant honey flow does not by any means occur every year but when it does occur, the beekeeper should be prepared to take full advantage of the opportunity.

Bees need so little attention during the greater portion of the year that it is difficult for the inexperienced beekeeper to realize that for the best results almost daily attention is needed during the few days or weeks known among beekeepers as the honey flow.



SAFE Lighting for any farm

Your home and stables are safer once you install this fine electric lighting plant. No longer need you fear fire from dangerous, musty oil lamps. Better light, too—indoors, outdoors, anywhere—at a turn of a switch. Fine for chores—no lantern to hold—saves time, means more fun, better health, *pleasure on the farm.*

DELCO-LIGHT

ELECTRICITY FOR EVERY FARM

Besides supplying all the light—clean, clear convenient light—that you need, Delco-Light provides power for small machines. Pumps your water. Does the washing and ironing. Chops feed, churns, runs the separator. Saves time and money—*pays its way.*

Delco Light is a simple, economical, complete electric plant. Comes ready to use. A child can operate it. Full details, illustrations and literature obtained by writing your nearest Delco branch. Prices—No. 205—$455, and No. 216—$585.

DAIRYING.

GOOD DAIRY COW EASILY PICKED OUT; WHAT TO LOOK FOR

The business of dairying has rapidly become commercialized during the last few years owing to the competition. While the prices for dairy products have increased in value during the last few years they have not increased in value in the same proportion that labor and feed have increased. For these reasons it requires a skillful business man at this time to milk cows at a fair profit.

Time Consumed in Milking

The average farmer milks his cows over seven hundred times each year and consumes on an average better than twenty-seven days in doing so. Is it any wonder then that the average farmer does not like to keep cows when he feels that they are not making him a good profit when it takes so much time and labor to care for them?

As each cow in the herd is different from every other one she must be fed and cared for in a different manner perhaps than the others to produce at her best. It requires judgment and skill to be able to feed and care for a cow so that she will produce the limit of her capacity and this capacity can only be acquired by careful, conscientious study and a close application of this knowledge in practice. Each cow should be cared for just as though she were a highly developed piece of machinery and then she will produce economically and profitably. In selecting cows for their productive ability, there are several essential features that usually show on the exterior of the cow and the man that buys a cow should be able to distinguish the most of these if he would secure a good one.

Characteristics of a Good Cow

There are a few characteristics that are found in every cow that is a good producer, being more or less pronounced according to the cow's productive ability. A cow to be a producer must have a good constitution, capacity to eat and digest large quantities of food, nervous temperament, which means that she must be an active worker and not a loafer, circulation means that she must have a large and well developed supply of blood flowing through the udder, from which the milk is secreted, and by ability we mean the power the cow has of secreting milk.

In selecting a cow it is always best to view the cow from the side and from some little distance, while she is standing with her side towards you, or while someone is leading her by you, as you are able in this way to get a very good impression as to her constitution and capacity, and do not forget that your first impression is usually the best. It is then well to walk around the cow to the other side, as cows do not always look the same from both sides, and then walk to the front, where a good view of the head, horns, eyes, and chest and barrel may be seen, and then step to the rear of the cow, where the udder and tail and width of hips may be seen. Then walk by the cow with one hand travelling along the neck and back, where the condition as to fat may be observed, while with the other hand the texture of the skin may be determined by grasping it and pulling it outward from the body. Next, milk the cow, or have someone else do so, and examine the udder carefully.

Some Good Indications

A soft, pliable, elastic skin indicates a good digestive apparatus, while a dry, harsh, clinging hide indicates poor digestion.

A cow, to be a good producer, must be a worker. She can not be a loafer. We have termed this nervous temperament, and we mean by that a highly developed nervous system that produces constant activity of the animal. A cow that is chewing her cud hwen she is not eating, and one that is always ready for her meals, and that always takes note of her surroundings. This is indicated by a large, wide forehead that slopes to the poll, and width between the eyes; also by prominent hips and ribs, and a lean, open-jointed backbone that is free from fat.

The udder of the high-producing cow is usually a network of veins and blood vessels, and the milk veins passing alon the abdomen are large and tortuous. The milk wells are larger and more numerous than in the light producer. The blood that flows through the udder determines the milk flow, and the udder that is attached high on the back and far forward along the abdomen has greater surface that is supplied with these vessels, and the flow of milk is correspondingly heavy. The thighs should be free from fat and form an arch, the widest part of which should be on the level with the attachment of the udder, which gives it plenty of space.

While it is always desirable to combine with the facts already given, symmetry of form and beauty, this is not always possible, and besides, it is no indication of greatness of production, as many of the best cows we have ever seen are more or less deficient in these two characteristics.

Size is not always an indication of the probable value of the cow as a producer, but it is many times taken as such, an indication by the inexperienced. Color is only a breed index, and is of consideration only in that light.

G. H. CONN.

THE USES OF SKIM MILK

A quart of whole milk weighs 34⅛ ounces, or a little more than 2 lbs., nearly 30 ounces of which is water. The remaining solid matter contains very useful food materials. Slightly more than 1 ounce is protein, a very important muscle builder, and one of the most expensive of the substances needed by the body. About 1 1-3 ounces consists of butterfat, and 1 2-3 ounces of milk sugar. These two materials are used by the body to provide it with energy, must the same as fuel is used to produce steam and power in the engine. The quart of milk also contains about one-quarter of an ounce of mineral matter, small quantities of which are very necessary for the growth and general upkeep of the body.

As the fat is separated to form the cream some of the protein, milk sugar, and mineral matter go with it, but by no means all. The protein remains; therefore a quart of separator-skimmed milk provides slightly more of this indispensable and costly material than does a quart of whole milk. It contains in all about 1 1-5 ounces of protein, 1¼ ounces of milk sugar, about one-quarter of an ounce of mineral matter, and a little fat, the last named depending, of course, upon the completeness of the separation. This means that, quart for quart, it would furnish the body with slightly more protein and milk sugar than whole milk does, and practically the same quantity of mineral matter, though far less fat. In other words, as a tissue builder it is equal to whole milk, and as an energy yielder not nearly so good. Since, as a rule, the tissue-building materials are contained in the more expensive foods (meat, eggs, etc), and the energy-yielding materials can be largely provided by cheaper foods (bread and other cereal foods, fats, potatoes, etc.), it seems doubly wasteful not to use skim-milk.

The uses of skim-milk are many and in cooking it adds to quality as well as to food value. If used in place of water in bread it adds about as much protein to one pound of bread as there is in an egg. Skim-milk used in place of the usual half milk and half water, of course, increases the quantity of protein in a loaf by the amount that is contained in half an egg. The saving involved in the use of skim-milk in bread, however, is small compared with that involved in its use in the preparation of cereals, for, while in bread the milk is only about one-third of the flour, in the preparation of cereals the volume of milk is usually three or four times that of the cereal. To cook a cupful of cereal in three cupfuls of skim-milk instead of three of water, adds as much protein as that contained in three eggs.

WHEN MILK IS MADE A DISEASE SPREADER

The kind of milk vessels one uses is very important in maintaining cleanliness about the dairy. Tinware with a few seams offers the least number of places for contamination to lodge, and makes the work of keeping the vessels clean much lighter. Seams flushed with solder are much more easily cleaned and offer fewer breeding places for bacteria than unflushed ones. If you already have pails and pans with acute corners and open seams, they can be easily rounded by heating a stick of solder and running the melted metal in the cracks. The time and labor will be quickly repaid in the ease and quickness with which they can be washed.

Tinware kept right and perfect is longer lived and more sanitary than rust covered containers. Rust spots give places for decaying material to lodge and germs work their way more easily into the soft metal.

Keeping the vessels used in handling milk as nearly sterile as possible, is a big advantage in supplying pure, sweet milk. Milk allowed to dry on the utensils is hard to remove and encourages more to stick to it. Rinsing with hot water hardens the fresh albumin onto the tin and makes

Try an Ad in the FARMER

it harder to remove than ever. A thorough rinsing with cold or slightly warm water before hot water is used, will remove a large part of the milk and prevent much of the burning on. Then scrub with a brush using moderately hot water and some washing powder. If the alkali powder is too strong it will tarnish the metal and give it a dull appearance. This does not harm the value of the pail except that it is harder to determine when clean. A brush is used in preference to a cloth because it digs out the crevices more thoroughly. A cloth soon becomes contaminated, foul smelling, and is in itself a germ spreader.

After washing rinse with scalding hot water and turn upside down to drain. Air is very necessary in keeping utensils sweet and pure, that are continually used for milk, so do not place the lids on milk cans until they have been exposed for some time and are entirely dry. Do not forget that sunlight is the best and cheapest sterilizer. Cans exposed to its light each day will seldom cause trouble.—C. A. G.

IS IT NOT CURIOUS?

—A grade cow, eight years old, near Woodstock, Ont., that freshened last November, has given in eight months 13,092 pounds of milk, average test over 3.2, spot cash value $288.57; she is still giving 34 pounds of milk per day, and is due in November again. Such a cow is a source of perennial pride to her owner; he weighs the milk from each cow he has, because he finds it pays.

But is it not curious that many dairymen never bother to weigh, and so remain quite hazy as to each individual's performance? It is curious, too, when you come to think of it, that so many are content to bother with a herd not one f which has any remote chance whatever of giving in a year even one-half of what this fine cow gave in eight months.

The immense possibilities for an increased flow of milk from cows selected on their actual records, bred right, fed well and handled sensibly, seem curiously enough, entirely undreamed of as yet by some dairy farmers in all provinces.

Milk record forms will be gladly supplied free of charge by the Dairy Division, Ottawa, to any one curious enough and enterprising enough to find out what each co wdoes actually produce in return for all she eats. Make each cow pay. C. F. W.

LIGHTING A COW BARN

The best lighting in a rectangular barn is secured when the barn extends north and south. Four square feet of glass per cow provides an amount of light commonly accepted as a standard. A wall containing a number of windows costs but little more than a wall of lumber or masonry.

Many bank, or basemen, barns are insufficiently lighted. Where basement barns are built on a side hill, the wall of the sfirt story that is next to the bank should extend above the ground far enough to allow windows to be placed in it, or the bank should be excavated. The windows should be placed in the upper part of the stable wall rather than the lower, even on the exposed sides of the barn, in order to admit sunlight farther into the interior, and to lessen window breakage by the cows. The windows should be placed vertically rather than horizontally, and located so that there is an even distribution of light.

CHURNING TEMPERATURES

A cream rich in butterfat will churn more easily than one of low test, and so requires a lower churning temperature for best results. Low temperatures are favorable for a firm butter, and this is why a cream rich in fat is so desirable, as it allows lower temperature for churning. Generally speaking, a cream testing about 30 per cent and yielding about 3½ lbs. of butter per gallon gives best results. The following table will serve as a guide, all other conditions being favorable:

Test.	Spring and Summer Deg. Fahr	Fall and Winter Deg. Fahr.
30%	48-54	50-56
18%	58-60	58-64
24%	53-57	54-58

The amount of cream in the churn and the speed of the churn also affect the churning. The fuller the churn the longer it will take. The churn should never be more than half-full. The speed of the churn should be such that the cream receives the greatest amount of agitation or concussion.

DAIRY COWS HAVE INDIVIDUALITIES

All dairy cows are not by any means the same. There is the difference between gain and loss, and then there is the inconceivable yield with its proportionate profit. There is the 28,000 pound cow, with her extraordinary profit, the 2,000 pound cow, with her loss, and there is the 8,000 pound cow, with her fair gain to her owner. Where is the difference? The poor or profitless cow is a cow to be sure, but let us be thankful that this kind is growing fewer and fewer. On the other hand, take the cow with the ability to give 10,000 to 12,000 pounds of milk in a year, and we have a cow that is a paying proposition, and of a standard that is within the reach of every progressive dairyman.

There is no doubt but that the propensity to give large quantities of milk is transmissible. There is no doubt but that the power to make and give milk can be increased and strengthened if the propensity be present. In athletics a good runner improves with training. In racing, a horse must needs be trained to improve the gait and to increase the speed. A race horse is also fed and cared for that he may be speedy. Why then cannot a cow by proper feeding, training, and care, be made to do that for which she was born? And if this or any other characteristic is developed in the dam it stands to reason that she will the more likely transmit it to her offspring.

Individuality in a cow is evidenced by superior development in all her parts, and the reappearance of these traits in her offspring. The prepotent sire imprints his individuality on his offspring with unmistakable exactness. Moreover, the individuality of the owner is shown in the cows of his herd. If we see a herd that is well cared for, and all of whose members bear resemblance to each other, we conclude at once that the owner has an ideal cow in mind, and that he is trying to build up his herd to a certain type.

Often we find a herd in which there is an old cow of superior merit, and along with her we find perhaps three or four or even more all having the same characteristics. The old one is the dam, granddam, great grand-dam, etc., of these, and her characteristics have been handed down to her offspring. If one has an animal of noteworthy qualities it will pay him to keep her and attempt to get more like her from her. A herd that as a whole shows a herd individuality is one to be greatly proud of if it is of a high grade.

These best dairy cows are those that will return the most value of milk for food consumed.

Milk, unlike many other products from the farm, must be dealt with according to fixed rules or loss will come quickly.

TUBERCULOSIS IN HOGS

Not everyone is aware that tuberculosis will affect hogs as well as cattle. While we in Canada have not found this disease general among hogs, it is nevertheless true that in certain districts it exists and is making headway. Buyers for packing houses can numerate certain districts in Western Canada from which hogs will not be bought for slaughter on account of the general prevalence of this disease. It is, therefore, in our interests to know as much about this disease as possible.

Farmers' Bulletin 781 recently published by the United States Department of Agriculture on tuberculosis of hogs, states that of the hogs slaughtered during 1916 at establishments under federal inspection, which includes all important ones, 9 per cent were found to be affected with tuberculosis. While this is the general average for the entire country, it is noticeable that a much larger per cent of diseased hogs comes from some sections than from others. For example, hogs from some of the southwestern states, such as Arkansas, Oklahoma, and Texas, are remarkably free from the disease. This is, doubtless, due to the fact that hogs in that section are pasture fed to a very large extent.

On the other hand, corn belt hogs and especially those from dairy states, are altogether too frequently affected with tuberculosis. While only 2.4 per cent of the 451,478 hogs slaughtered at Fort Worth, Texas, during 1915 were tuberculous, 8 per cent, 10.9 per cent, 12.1 per cent, and 25.1 per cent respectively of those slaughtered at four cities in a leading dairy state showed tuberculous lesions.

From this it is evident that the subject is of importance to dairy farmers and especially so since the above mentioned bulletin reports that packing houses are beginning to discriminate against hogs from localities known to be badly infected.

The most frequent infection of hogs occurs through the digestive tract and is intimately related to tuberculous cattle. In those localities where a large number of hogs have been found affected with the disease, investigation showed that most of the hogs in question had been fed upon unpasteurized skimmilk or occasionally that the carcass of some animal succumbing to the disease had been thrown to them to dispose of. Another source of infection is the practice of allowing swine to run behind tuberculous cattle. Still another is the infection of young pigs through the milk of a tuberculous sow, but to dairymen, at least, the first is of most importance.

Experiments have been conducted to show that milk from cows affected with tuberculosis will produce the disease in swine. When hogs were fed such milk for only 3 days and held for 107 days more, 83.3 per cent of them showed tuberculous lesions when slaughtered. Of those fed tuberculous milk for 30 days and then allowed to live 50 days longer; 100 per cent developed generalized tuberculosis.

Nor is this true of experimental cases only. In one instance a shipment of 74 hogs showed tuberculosis in 61 and investigation brought out the fact that the hogs had been fed skimmilk from a creamery in a nearby town. The separator slime from the creamery contained tuberculous bacilli.

Accordingly, unpasteurized skimmilk from creameries is not generallf a safe feed for hogs. Neither is unpasteurized milk from the farm separator safe unless the herd is free from the disease. The creamerf skimmilk is more dangerous only because it is the mixed product from numerous herds, any one of which may be infected, and because it in turn may be fed to a number of lots of hogs rather than one, thereby doing greater damage.

One remedy for this is, of course, to feed only pasteurized milk but even that will not suffice because hogs working over manure from tuberculous cattle will contract the disease. The only sure remedy, then, is to clean up the dairy herd, make sure it is kept clean by testing regularly, and get rid of any brood sows that may have the disease.

HOW TUBERCULOSIS SPREAD IN HERD BY CLOSE CONTAMINATION

At a number of the recent meetings of men interested in live stock, the question of tuberculosis has been discussed. The subject of ventilation in one which is always brought up in connection with such a discussion.

NEPONSET

BIRD NEPONSET PRODUCTS

Paroid

BIRD NEPONSET PRODUCTS

ROOFING

Look for the Roll with the Paroid Label

Best for Barns

Paroid makes the best roof, and is not expensive, costing about as much as good wooden shingles. Paroid cannot rust, rot, split, or dry out as other roofings do. You can lay a Paroid roof then forget about it.

Resists Fire Burning sparks and embers falling on a roof of Paroid die out harmlessly. Many a building has been saved from fire and destruction by this roofing. Approved by the National Board of Fire Underwriters.

Complete Kit—Ready to Lay When you open a roll of the genuine Paroid, you find a complete kit inside, with full instructions and our unconditional guarantee. No roofing is easier to lay than Paroid, and the farmer needs no helpers, other than those on his own farm.

Insist on the Genuine Paroid Do not let any dealer give you a substitute for Paroid. Look for the label on every roll you buy. Remember, Neponset Paroid Roofing is used by the Dominion Government, the railways, and by farmers all over Canada. Remember Paroid roofs have given service for over nineteen years. Insist on the genuine.

Neponset Paroid is made in Grey, Red, and Green—handsome permanent colors

For your Home, use Neponset Twin Shingles, of the same good quality as Paroid, surfaced with crushed slate, Red, and Green.

Hardware and Lumber dealers sell our roofings. Look for the Neponset dealer and get good satisfaction.

PULVERIZED LIMESTONE

SWEETENS THE LAND AND PRODUCES HEAVY CROPS

The demand last season for our "Clairmont" Brand Pulverized Limestone was so heavy we were unable to fill a great many orders. We expect a very heavy business for 1918 and would advise all booking now and getting their supply early. Our Limestone is showing wonderful results.

Works at TORRYBURN, on C. G. R.

The statement was made at these meetings by men, who are very prominent in live stock circles, that by proper ventilation the spread of tuberculosis in our herds could be greatly retarded; in many instances the inference has been made that the spread of the disease could be almost entirely stopped if the ventilation of the stables was what it should ge. It seems to the writer that a mistake is being made in this regard, and that many breeders and farmers will be led astray by such statements. There is no question but that barn ventilation should receive the earnest attention of the farmer, and that he should make every attempt possible to keep the air of his stables in a satisfactory condition, for certainly this will tend toward the maintenance of good health in his animals. It is likewise certain that when an animal is in a thrifty condition it is less likely to acquire a disease than if it is weakened by any cause whatever.

The most thorough ventilation can, however, have but little influence in preventing the spread of tuberculosis. The organisms causing the disease are eliminated from the body of the diseased animal in material that is coughed up from the lungs, and which in part is ejected from the mouth during the act of coughing. The infectious material, thrown into the air, may float for a short period of time. Thus opportunity is presented for the organism to be carried from one animal to another. The material will also be brought in contact with the mangers, and when feed is placed in the mangers there is, of course, opportunity for the infectious material to be distributed. Allowing water to flow through the mangers, and processes of cleaning likewise serve to spread the disease-producing organisms. The organisms are also eliminated from the body in the feces. Some portions of this material become dry and ground into such fine particles that in cleaning and bedding the stables the organisms find their way into the air, and may thus be spread throughout the stable.

The material that is coughed up from the lungs of the animal serves to contaminate the mouth and tongue, and when the animal licks herself her coat is very likely to become contaminated with the tubercule organism. When other animals are brought in direct contact with her, as will happen in the yards and pastures, there is ample opportunity for the disease to spread in the herd.

It will be seen that there are certain factors in the stable, operating to spread the disease, that are not kept in the stable. For example, the chance of the disease organisms being spread through the air, when they have found their way into it through the coughing of the animal or in dust, is present in the stable, while it is almost wholly absent when the animals are out of doors. The contaminated manger is another stable danger which is absent when the animals are on pasture, since there is very little likelihood of organisms, which have come in contact with the grass, persisting for any length of time in the direct sunlight.

The only direct retarding influence that vetnilation of the stable can have is through the partial removal of organisms which may be present in the air. It can have no influence as far as contaminated mangers are concerned. From our present knowledge of the way in which tuberculosis is spread from one animal to another, it seems certain that stable ventilation will be a very minor factor in retarding the spread of the tubercle bacilli from animal to animal and that the man who places confidence in it as a means of preventing the spread of tuberculosis in his herd is certain to be disappointed.

It seems to the writer that everyone should know what any particular agent or process can do for him and he should likewise be as familiar with what it cannot do for him. So adequate ventilation of the stable is certainly desirable from every point of view, but it will not prevent the spread of tuberculosis in a herd, and it is questionable whether it will have any measurable influence in retarding the distribution of the disease. The rapidity with which this disease spreads among animals which are kept out of doors constantly is evidence of th esmall importance of the factors that are operative only in the stable.

Proper stable ventilation is required for the conservation of the health of live stock. Lack of proper ventilation will tend to make cattle less resistant to disease because it diminishes their bodily vigor. No argument can be advanced for not providing proper ventilation of stables. However, in attempting to prevent the spread of tuberculosis, men cannot rely alone upon ventilation. Ventilation should be accompanied by an inspection of the herd and the constant use of the tuberculin test and the elimination of all reacting animals.

WATCH FOR ILLNESS AMONG THE LIVE STOCK

It should be the rule on every farm to watch the live stock carefully to detect any appearances of illness. The stock should be watched at feeding time, and if any animal shows signs of not eating naturally, it should be immediately isolated from the remainder of the herd or flock. Not all animal diseases are contagious, but many of them are, and it is well not to run any risks. Even if there is no danger of spreading disease, a sick animal stands a much better chance for recovery, if placed where it will not be annoyed by the other stock, for it is the nature of almost any animal to drive and injure another animal that does not act naturally. It is probably brute instinct that causes an animal in a herd to want to isolate a sick animal. It seems sometimes the well animal is more thoughtful than is the owner of the herd, for he is not so quick to detect an ill animal and slower yet to plan for its removal from the lot. The same rule holds good with the poultry and many a case of contagion can be checked by quickly isolating the sick birds.

Watch the little pigs for sore mouth. If ulcers are found isolate the litter and treat the affected pigs. Tincture of iodine on a cotton swab used daily will be valuable. If the disease is far advanced the pig should be destroyed and the carcass burned. Write the Colorado Experiment Station if you are having trouble. Let us conserve the little pigs.—I. E. Newsom, Colorado Agricultural College.

IMPROVE YOUR FARM

Add to its profitableness as a business, its comfort as a home and its value as an investment by modernizing it with

PEDLAR'S "PERFECT" SHEET METAL PRODUCTS

Pedlar's Corrugated (Galvanized) steel siding and "George" Shingles for modern barns, and Pedlar's Silo Covers.

Pedlar's "Stone or Plain Pattern Siding" and "Oshawa" Shingles, for beautiful, fireproof, enduring homes.

Pedlar's Metal Ceilings and Walls for the interior—2000 handsome patterns—last as long (without repairs) as the house itself.

Delapidation rapidly overtakes any wooden structure. Any day fire may destroy it. Every thunderstorm brings the menace of lightning. But if you build with Pedlar's Sheet Metal Products you have buildings that will endure long years without repair and that are practically immune from lightning or other accidental cause of fire.

Pedlar's Toncan Metal Culverts for farm drainage are unexcelled. Last longer than the road they run under. Easily and quickly installed by anyone.

WRITE FOR BOOKLET "M 7"

illustrating and describing Pedlar's Sheet Metal Products for the farm

Pedlar's Portable Garages for the car, and quickly erected buildings for housing implements, etc., are conveniences highly appreciated.

Pedlar's Sheet Metal Products are the true farm economy. They mean freedom from excessive first cost. They reduce repair bills to the lowest ebb. They constitute a permanent improvement that benefits you whilst you work the farm and make it easier for you to get your price when you are ready to sell.

THE HORSE

IN TREATING SORE SHOULDERS USE SIMPLE REMEDIES

From the time farm horses are put to work in the spring until all farm work is finished in the fall, thousands of work horses suffer with sore necks and shoulders. These sores not only interfere with the general usefulness of the animals, but frequently leave a collar boil or fistulous withers, which usually demands a surgical operation and lays the horse off for a month or more.

Causes

The causes of sore necks and shoulders may be classed under two heads, namely; sores caused by pressure, and those caused by friction.

Sores caused by pressure result from the pressure of a load on the wrong part of the neck or shoulders. This occurs when the collar is too tight, when the draught is too high or too low, when the collar or pad has an uneven surface, or when the horse carries a heavy weight like a wagon or binder tongue on his neck.

Other sores are the result of the rubbing of the collar on the neck or shoulders. This may occur when the collar is too large. Then with every step there is a tendency for it to slip and slide on the neck and shoulders and a sore is inevitable. Collars may fit fairly well but when the horses carry a rapidly vibrating tongue like that of a mower or binder, the sores are more easily produced.

Prevention

Prevention is simple and not difficult to carry out. The collar must fit. The draught must be properly adjusted. The bearing surface of collar and pad must be kept clean. Horses having sore necks or shoulders must not be worked on mower or binder unless provision is made to remove vibrations and weight from the tongue. The irritating effects of dust and sweat may be overcome by removing the collars at noon and sponging them and the horses' necks with clean cold water. This should also be done every evening when the harness is removed. Colts and idle horses must have their necks and shoulders gradually hardened, the process extending over a period of several weeks. When a horse is in good physical condition his neck and shoulders are fuller than when he is thinner, consequently if a collar fits when a horse is in good condition, it is likely to be too large when he has been worked several weeks. Some careful horsemen find that it pays to have collars of two sizes, using the large collars until the necks shrink, and then using the small size. Other good horsemen use pads to reduce the size of the collar when the neck shrinks. Still others make a practice of allowing their teams to rest a few minutes several times each half day, and while doing so slip the collars far enough forward on the necks to allow both collars and necks to cool and the shoulders to rest. This is an excellent practice and is worth adopting.

How to Fit a Collar

The collar should fit the horse's neck. It is impossible to fit the neck to the collar. It should be wide enough throughout its entire length so that it will not pinch the neck. There should be room enough to pass your finger tips from the top pad to throat between collar and the hores's neck. It should be long enough to allow the palm of the hand to be slipped under it at the throat.

When the proper size of collar has been selected, it should be fitted to the neck of the horse that is to wear it. The best way to do this is to soak the collar in clean water for a short time, and then while it is still soft and pliable put it on the horse that is to wear it. Work him wearing this wet collar for several hours, so that it will be fitted to the contour of his shoulders. Then remove the collar and allow it to dry thoroughly, after which it should not be worn on any other horse.

Medical Treatment for Sore Necks

The simplest remedies usually yield best results, providing the points just outlined receive proper attention. Common white lead ground in linseed oil, the kind used for mixing paint, is very good. Apply a small quantity of it every evening. Oxide of zinc ointment is also very satisfactory, when applied every evening. A lotion composed of six drams of lead acetate, and an equal amount of zinc sulphate in one pint of water makes an excellent wash for sore necks and shoulders. Stable hygiene has an influence on the healing process. Clean, light, airy stables, free from dampness and the fumes of decomposing manure are much more favorable to the healing process than stables in the opposite condition.

In a word, prevent all sore necks and shoulders possible. This is better than a cure. Secure prompt healing of those cases that are not prehealing so favorable that nature has ventable by making conditions for healing so favorable that nature has but one course to follow, namely to heal promptly and completely.

C. C. LIPP.

CEMENT FLOOR FOR HORSE BARN

I have had cement floors in my stable for three or four years, and during that time have kept horses of different ages and dispositions; mares in foal and young colts, and am well satisfied with this floor. I have taken colts off summer pasture and kept them on the cement floor during winter with the best of results. Even at the first there was no stocking or swelling of the ankles. I now have a mare that paws the bedding back and stands directly on the concrete. She does this most of the time, but is not made stiff or injured in any way that I can see. This mare is troubles with dry hoofs, and some blacksmiths claim the concrete causes this, but as I have known the mare ten years, and her hoofs were the same when she stood on a plank floor, I see no reason to blame the concrte.

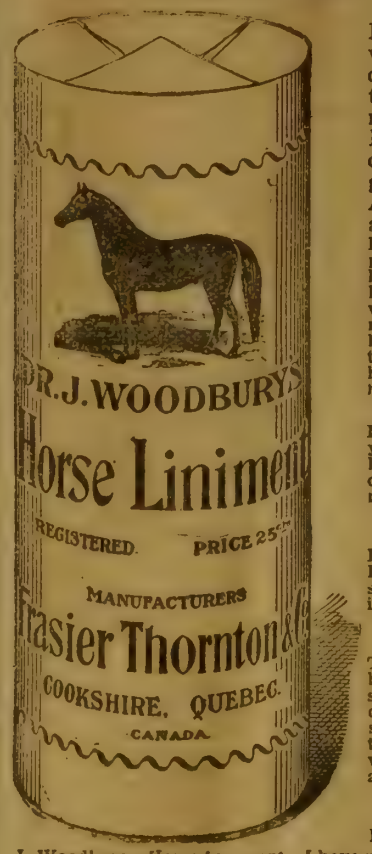
It may be, as some claim, that the ideal floor for horses is clay, but the trouble is, horses will paw holes in it, and there is certain to be some loss of liquid manure. Then, too, it is hard to keep clean. The cement is easily cleaned, and where sufficient bedding is used to absorb the liquid, there is a saving of plant food. I find more bedding will be required with concrete than an open plank floor. No farmer should object to this, however, as it is a saving and not a loss. Cement prevents underdraughts, and is therefore more comfortable for the horse.

In making our stable floor we filled in with stones and coarse gravel up to the last 6 or 8 inches, then we used a mixture of some 5 parts gravel, 2 of sand, and 1 of cement. The last 2 inches were made richer with less gravel. Use clean material and tamp well to keep from settling or cracking the top. Tamp well each layer as put in (this is important), and leave the top rough so horse will not slip on it. We make a slope of 3 or 4 inches from front of stall to back to drain so the liquid will mix with the solid manure, and be cleaned out together. R. M. T.

Butter is a condensed product. Nothing can be made or grown on the farm which brings as much per pound.

Dr. J. Woodbury's Horse Liniment

THE INFALLIBLE REMEDY



For the removal of Splints, Bog Spavins, enlargements of any and every description it has no equal. Given internally, it will promptly relieve and remove any and every character of Cough Enlargements of the Glands, Affections of the Kidneys. For distemper, strangles, and colic it is infallibly the remedy All horses that are stabled should have an application of Dr. J. Woodbury's Horse Liniment to the hoofs of the forefeet to prevent their becoming feverish, dry, brittle, hard, contracted or otherwise injured Insist on having Dr. J. Woodbury's Horse Liniment. We warrant it to effect that for which it is recommended when used according to directions. Its beneficial effects are so prompt and decided that it has excited the admiration of the leading horsemen of the Dominion and secured their highest confidence.

Bear River, N. S.
Dear Sirs:—We do not hesitate in recommending your Dr. Woodbury's Horse Liniment. We have used it in the woods for coughs, colds, distemper and cuts and would say that no lumberman should be without it.
Yours truly, Clarke Bros.

Hubbard's Cove, N. S.
Dear Sirs:—I have used Dr J. Woodbury's Horse Liniment in my stable for years and consider it the best liniment on the market for both internal and external use.
Yours truly, C. C. McLean.

Truro, N. S.
This is to certify that I have used Dr. J. Woodbury's Horse Liniment with the very best results for colds, coughs, distemper and all lung deseases. It is the best to give horses in the spring to keep them in condition. It purifies the blood, cleanses the lungs from impurities which may exist and gives the system healthy action.
Newton Lee, Owner "All Right" 5817.

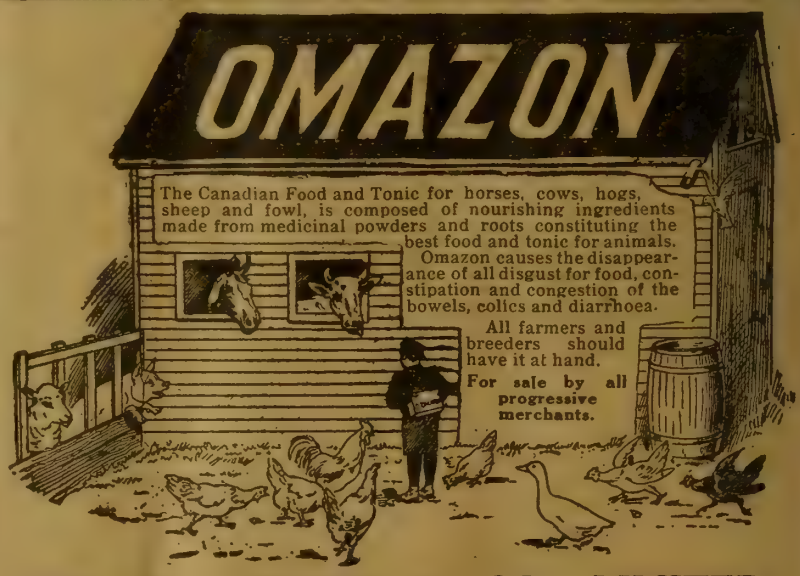
Elmsdale, N. S.
Dear Sirs:—Kindly send me 6 dozen bottles Dr. J. Woodbury s Horse Liniment. I have not a bottle in the store and it is the only kind my customers will take. Yours truly, Elmsdale Mercantile Co.

Elmsdale, N. S. Dear Sirs:—I cured my horse with Dr. J. Woodbury's Horse Liniment. It was a bad case of distemper. I always recommend this liniment to my friends as the best for all diseases of the horse. Yours truly, H. R. Whitehead.

Dear Sirs:—One of my horses had a bad cough and I made a complete cure with three bottles of Dr. J. Woodbury's Horse Liniment. The cough was of twelve months standing. In my large experience with horses I consider this liniment to be the best made for all diseases in the horse, I recommend it to my friends. E. J. Anderson, Truro, N. S.

FRASIER THORNTON, & CO., Limited, Manufacturers: Cookshire, Quebec, Canada

OMAZON



The Canadian Food and Tonic for horses, cows, hogs, sheep and fowl, is composed of nourishing ingredients made from medicinal powders and roots constituting the best food and tonic for animals.
Omazon causes the disappearance of all disgust for food, constipation and congestion of the bowels, colics and diarrhoea.
All farmers and breeders should have it at hand.
For sale by all progressive merchants.

DR. ED. MORIN & CO., LIMITED,
QUEBEC, CANADA

GILSON—"JOHNNY-ON-THE-SPOT"

THIS ENGINE only $49.50

A BIG, little engine, that *"Goes Like Sixty"* at every light and medium heavy job on the farm. A heavy worker, and a light eater—dominating in Quality and Service. The biggest selling engine of any size in Canada—quantity production enables us to undersell all competitors—raising the quality, and lowering the price.

Do not buy a cheap engine—buy a good one at a quantity price. All sizes at proportionate values. Write to-day for free catalogue stating what size engine interests you.

POULTRY.

VALUE OF WATER IN POULTRY RATION

Through various experiments with poultry at various times and places it has been found that water is a necessity and a requisite to a laying fowl. It has been demonstrated that should the water supply be removed from a pen of fowls, the egg production would be reduced at least fifty per cent. Hens consume an enormous amount of water if one will give the subject a little extra thought. The average farm flock of from 100 to 150 fowls will consume nearly five gallons of water daily. It is averaged that each fowl will consume 8 ounces of water during a day. This means one gallon daily to 16 hens.

Taking the hen's viewpoint, water is just as important as feed. It is as much of a requisite for egg material as food, for she cannot make an egg with either one alone. Hence, we can easily see that the man who is feeding a good amount of costly feed but who is neglecting the all-important water supply, is making a great mistake, and will have to be contented with a low egg yield.

Considering the present high prices of feed, together with the weather conditions, hens will consume about six gallons of water to each one dollar's worth of food. Therefore, if the feed is worth one dollar, the water is worth the same amount. We have seen that fowls need water, but we have not understood why. Let us find out now by enumerating the uses to which the hen puts the water:

First, the water is used to soften solid foods in preparing for digestion. We all know well enough that hard, solid foods have to be softened by some process before it can be digested.

Water must be given to supply the liquid element of the blood, which carries the nourishing atoms of food to all parts of the body, supplying worn-out organs with stimulating food, and carries away from these exhausted tissues all poisons and excretive wastes.

When we know that an egg is 75 per cent. water we see that it is impossible for a fowl to make an egg unless we supply plenty of water for her to drink, for she cannot make eggs unless the elements that compose the egg are sufficient.

Water equalizes to a greater extent than anything else the temperature of the hen's body. Cold water lowers the temperature, and warm water increases the heat, and for this reason we give our fowls the former in warm weather, and the latter in cold weather. A fowl's body is also cooled by evaporation, as is also the human body. In the human body evaporation is accomplished through perspiration. A fowl does not sweat, but the temperature of her body is reduced by evaporation through her breathing organs. This accounts for the hen holding her mouth open and breathing so rapidly on a hot summer day.

From the foregoing talk on water as a factor in egg production, we learn two great lessons that will mar success if either is neglected. Water is just as important as feed. Once a day is not often enough to water our pen of fowls. W. G. Pickens.

It is cleaimed that 100 pounds of fresh hen manure contains about 50 pounds water, 16 pounds organic matter, 56 pounds ash. Analysis shows that poultry manure contains 2.43% phosphoric acid, 2.26% potash, and 3.25% nitrogen, as ammonia and organic matter.

Help Wanted!

These moulting fowls need help. You can supply the necessary strength to expel the old quills and shorten the moult by giving them

Pratts Poultry Regulator

It regulates the blood, bowels and digestive organs. Tones up the entire system. Strengthens the egg-producing organs. Promotes early fall and winter laying.

Put up in popular-priced packages, also in money-saving 25-lb. pails and 100-lb. bags. Ask your dealer.

Money Back If Not Satisfied.

Our new book, "Poultry Wrinkles," tells how to shorten the moult. Write for it. It's FREE.

FOR HOME AND COUNTRY

This Department will be utilized to the best interests of the homes in the Maritime Provinces. Subjects relating to household science and all that stands for better homes and communities will be published on this page. The editors, Misses Saunders and Winter, of Fredericton, N. B., solicite your assistance in making this page a success and will be glad to publish tested recipes, household discoveries and other articles useful to the homemaker and women's organizations.

GROWN UP

"I looked at him a little while ago
And thought, how much he does begin to grow,
And yesterday he measured to the span
Full five feet six—the youngster is a man!
Grown up Lord help us, but it makes us wince
To look at him and think a short while since
He was a boy in breeches to the knee,
And now he's got a girl he goes to see!

They'll shave him next, and make a dude of him,
And tog him out regardless. Eyes grow dim
Along the vistas of the far-off days,
And there amid the vision sometimes plays
A little tike, all curly gold on hand,
With kilts of plaid, and little shirts with bands,
With bands with buttons on them where a mother's hands
Buttoned his breeks with patience. Now he sands
A half head taller than I am myself—
Ambitious to be off and earn some pelf!

This is life for you! To bear, to bring
Our hearts to love them as with brooding wing
Above their couches we bend down in prayer—
And then some day they are no longer there,
But walking with us in our dark and light,
Like men and women—staying out at night,
Gathering their own ideas, of age and free,
And only our dreams still left to you and me!"

THE VALUE OF FOODS TO THE HUMAN BODY

Just how much food the human body does need is a complicated problem to which in recent years scientists have been devoting much attention. Food is the source from which the body derives both its energy, or fuel, and the substance it uses to build and replace worn-out tissues. It also provides small amounts of recently discovered substances needed to regulate growth and other bodily functions. As a unit for measuring the energy supplied, scientists have adopted what is known as the calorie, and it is estimated that for a full-grown man engaged in moderate physical work, 3000 calories a day are needed. Of these, from 300 to 400 should be supplied in the form of protein, the chief substance utilized by the body in tissue building. There should also be some fruits and vegetables which supply the mineral matters needed for building tissues and help in various ways to keep the body machinery in good working order; also fat and starches and sugars which are valuable sources of energy. The energy supplied by the foods as a whole is consumed by the body in running itself and performing its daily work.

The number of calories and the amounts of nutrients contained in stated quantities of different kinds of food have been worked out by scientists and afford a basis for comparing the nutritive value of various dishes. The matter is so complicated that the ordinary housewife probably has neither the time nor the inclination to make a mathematical calculation of the nourishment her meals afford. It will, however, help her to know that by observing a few fundamental principles she can alter her bills of fare to suit changing conditions at home or in the market without any risk of underfeeding the family. First among these is the fact that an adequate diet should contain articles from each of the five groups into which the common food materials may be divided:

These are: 1—Vegetables and fruits which supply acids and other substances that the body needs to keep it in proper working order, as well as some building materials and energy. 2—Meats, fish, eggs, milk, legumes, etc., in which the proportion of protein to other substances is high in comparison with the other groups. 3—Starchy foods like potatoes, rice, flour and other grain products, etc., which furnish much energy and some protein and mineral matters. 4—Foods rich in sugar, an excellent source of body fuel, the pleasant flavor of which makes the diet more attractive; and 5—the fats, like butter, bacon, cream, lard, etc., which are valuable sources of energy.

No one of the groups can profitably be omitted altogether. It is, nevertheless, possible to avoid from a nutritive point of view a useless waste of money by selecting, first, the cheapest articles in each group; and second, by substituting to a certain extent articles from a cheaper group for those from a more expensive. In particular the grain foods in Group 3 may be used more extensively than is common in many households, and the use of the higher-priced ones in Group 2 may be correspondingly decreased. The grains furnish protein as well as energy, and in a cheaper form than meat. By combining them with a little meat, the meat flavor is secured and a dish as nutritive but much less expensive than meat alone obtained. This does not mean that all animal foods or even all meats should be cut out of the diet entirely. As far as can be judged, in the light of our present knowledge, the body is most likely to keep in health if it obtains its protein from a variety of sources, including milk (especially in the case of children), eggs, meat, etc. Similarly, dried fruits contain not only the characteristic rpoperties of foods in Group 1, but sugar as well, and a liberal use of them will provide in an economical form, much of the sugar which the palate craves.

The husewife, too, who understands these and similar facts in regard to the composition and uses of food will be able to free herself from many existing prejudices. Skim milk, for instance, is regarded as unfit for human use. As a matter of fact, it contains practically all of the constituents of while milk except the fat taken off in the cream. On farms it is frequently fed to livestock, but in many cases it might be more economical to use in the household. If it is considered too thin for drinking, it may be used in cooking, as in making soups, mixing bread, or cooking cereals.

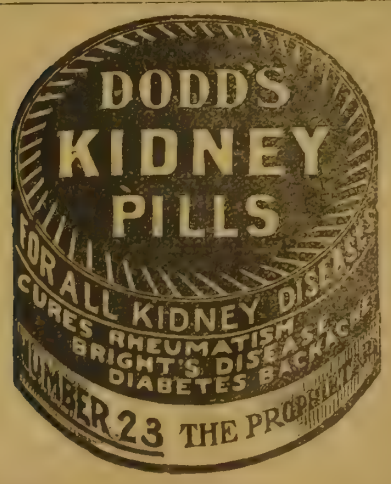
HOME-MADE COOK-STOVE DRIER

DIMENSIONS: Base 24 x 16 inches: height 36 inches. A base, 6 inches high, is made of galvanized sheet iron. This base slightly flares toward the bottom and has two small openings for ventilation in each of the four sides. On the base rests a box-like frame made of one or one and a half-inch strips of wood. The two sides are braced with one and a quarter-inch strips serving as cleats on which the trays in the drier rest.

These are placed at intervals of three inches. The frame is covered with tin or galvanized sheet iron, which is tacked to the wooden strips of the frame. Thin strips of wood may be used, instead. The door is fitted on small hinges and fastened with a thumb-latch. It opens wide so that the trays may be removed easily. The bottom in the drier is made of a piece of perforated galvanized sheet iron. Two inches above the bottom is placed a solid sheet of galvanized iron, three inches less in length and width than the bottom. This sheet rests on two wires fastened to the sides of the drier. This prevents the direct heat from coming in contact with the product, and serves as a radiator to spread the heat more evenly.

The first tray is placed three inches above the radiator. The trays rest on the cleats three inches apart. A drier of the given dimensions will hold eight trays. The frame of the tray is made of one-inch strips on which is tacked galvanized screen wire, which forms the bottom of the tray. The tray is 21x15 inches.

The lowest tray when placed in the drier is pushed to the back, leaving



a Present *for the* Soldier

YOU can depend on the mothers to think of the little things which will be appreciated by the boy in the camp or trenches. And one article which many a mother has given her boy at the last moment is Dr. Chase's Ointment.

There are so many ways that Dr. Chase's Ointment is useful to the soldier that it becomes invaluable to him. It is used for chafing and skin irritation resulting from heavy clothing and equipment. It brings comfort to sore, scalded feet after the long march. Applied to wounds it prevents blood-poisoning and heals the skin. And it should never be forgotten that Dr. Chase's Ointment is the most effective treatment obtainable for piles, a distressing ailment which results from contact with the cold earth, whether in camp or trench.

The Canadian soldiers have been well supplied with this standard ointment, and, judging by their many letters of appreciation, there seems to be few things more keenly appreciated. Just try it in the next parcels you send to the front.

Dr. Chase's Ointment

60c a box, all dealers, or Edmanson, Bates & Co., Ltd., Toronto. Refuse to accept substitutes, for they only disappoint.

the three-inch space in front. The next tray is placed even with the front, leaving a three-inch space in the back. The other trays alternate in the same way. A ventilator opening is left in the top of the drier, through which the moist air may pass away.

The principle of construction is that currents of heated air pass over the product as well as up through it, gathering the moisture and passing away. The movement of the current of air induces a more rapid and uniform drying. The upper trays may be shifted to the lower part of the drier and the lower trays to the upper part as drying proceeds, so as to dry the product uniformly throughout.

If drying is done in a cookstove oven, leave oven door ajar. Note temperature of oven often. Trays for use in the oven may be made by using a convenient-sized piece of galvanized wire screen and bending up the edge one or two inches.

WOMEN'S INSTITUTE MEETINGS

In the Clifton hall, on the 23rd August, the Women's Institute held an "Old-Fashioned Tea and Concert", which was well pratonized by people from far and near. The menu consisted of dishes popular in ye olden days" some of the delicious eatables served, including: Molly's scallop, home-made bread and rolls, Aunt Jemima's pancakes, Sally's corn muffins, cottage cheese, Angelina's tea cakes, Aunt Betsey's gingerbread, grandma's cookies, tea, coffee.

On exhibition were one dozen quilts at least one hundred years old, such pretty designs too, that one felt tempted to buy, but as one lady said, "No indeed they are not for sale; we prize them too highly to sell them. However, we will be glad to sell you a ticket on this quilt recently made by the Institute members, and this rug so beautifully woven by one of our members," money for tickets was immediately produced.

One thing very much in keeping with the celebration was the old-fashioned spinning wheel on the platform in the hall, kept busy by a lady over eighty years of age. This was a pretty sight, and when conversing with the "centre of attraction" she said she "thought the Institute might have charged a fee to see her demonstrate.

In the evening, when the tea dishes were cleared away, a concert consisting of readings, vocal and instrumental music, all selections of years gone by, was delightfully listened to by all, and immediately following the concert Miss Winter, the Supervisor o fWomen's Institutes, threw on the screen many beautiful pictures of scenery she had seen on her trip West and North, including pictures of mountains, glaciers, totem poles, rivers and lakes, etc.

At the home of Miss Celia Peck, president of the Hopewell Hill Institute, a district Convention was held in July, the visiting branches being Albert and Hillsboro. Mrs. G. M. Russell, the vice president, welcomed the visiting members and splendid addresses were given by the three presidents. After the meeting a delicious luncheon was served and when a generous sized cake made its appearance, some one whispered, "the frosting is in the Institute colors." The "guest" presidents were asked to cut the cake. Everybody had such a good time, the officers of the Hillsboro Institute "put their heads together" and said "we will invite the Albert and oHpewell Hill members to meet with us in September" and sure enough the invitation was extended to them. Now, another enjoyable meeting is being looked forward to.

In honor of one young lady in the Hpewell Hill Institute, who is soon to change her name, an "At Home" was held at the home of Miss Celia Peck, the persident, in August. The entire membership was present and responded to roll call with quotations appropriate to the occasion. A letter which gave pleasure to all the members was read from a Candaian mother expressing her gratitude to the Institute for remembering her son, who is a prisoner of war in Germany. Following the business session, a very entertaining programme was carried out, consisting of vocal and instrumental music quite in keeping with the occasion. Miss Archibald was then presented, by the president, with a Pryex casserole, on behalf of the Institute. The guests then repaired to the dining room where a sumptuous luncheon was served, the centrepiece being a bride's cake iced with a design of roses, horseshoes and true lovers knots, entwined with smilax and surrounded by a vase of white sweet peas. This cake was afterwards presented to the bride-to-be.

A Place to Sun the Milk-Cans.—It is often a question to a farmer's wife to know just where to sun and air the milk pans, pails and cans. The contrivance which I saw recently near a kitchen door solves the problem nicely. It was simply an old wagon-axle driven part way into the ground with a large wheel on the upper end. The tinware was spread about on the spokes.

A Cutlery Holder.—More convenient than the usual kitchen drawer is a cutlery holder made of demin. Make a pocket sixteen inches long and about ten inches wide. Stitch in varying lengths, making places for large and small spoons, knives and forks. Tack this over the kitchen table, and when you are cooking you can easily find the article you wish to use.

So Bad With Kidneys Would Faint Away.

DOAN'S KIDNEY PILLS CURED HER.

Mrs. Albert Williams, Edam, Sask., writes: "I have the greatest pleasure in telling you what Doan's Kidney Pills did for me.

Ten years ago I was so bad with my kidneys that I would faint away and could not stand to do anything. I had been that way for two years, and had done all I could, but did not get any better until one day some one put a little book in our door, and I saw how another young girl had suffered like I was then, so I thought I would try them, and I am glad to say that after taking four boxes I have never had the same thing again, thanks to Doan's."

Doan's Kidney Pills are the original pill for all kidney troubles. They are put up in an oblong grey box, and bear the trade mark of a "Maple Leaf". See that you get "Doan's" when you ask for them.

Price 50c. per box at all dealers or mailed direct on receipt of price by The T. Milburn Co., Limited, Toronto, Ont.

THE ST. STEPHEN EXHIBITION

Toulouse—1 and 2, Aubrey Stevenson.

African—1, J. E. Conrod, St. Stephen; 2, D. Hyslop.

Common—1, J. A. Joudry, Waweig; 2, Martin Reid; 3, Fred Coffee.

Toulouse, 1917—1 and 2, Aubrey Stevenson.

DYSPEPTIC FOR SIX YEARS

Halifax N.S. Sergeant tried everything on the market, but Only Cure was Dr. Cassell's Tablets.

Sergt. Duncan MacNeil (home address 116, Pleasant-street, Halifax, N.S.), writing from Europe says:—"For six years I suffered from frequent attacks of Dyspepsia, and though I tried all the remedies on the market I obtained little or no relief. I had not been long with the C.E.F. when my old trouble returned. Then a friend told me about Dr. Cassell's Tablets. The first box brought such pronounced relief that I continued, and to make a long story short, complete cure was effected."

A free sample of Dr. Cassell's Tablets will be sent to you on receipt of 5 cents for mailing and packing. Address: Harold F. Ritchie and Co., Ltd., 10, M'Caul-street, Toronto.

Dr. Cassell's Tablets are the supreme remedy for Dyspepsia, Kidney Troubles, Sleeplessness, Anaemia, Nervous ailments, and Nerve paralysis, and for weakness in children. Specially valuable for nursing mothers and during the critical periods of life. Price 50 cents per tube, six tubes for the price of five, from Druggists and Storekeepers throughout Canada. Don't waste your money on imitations; get the genuine Dr. Cassell's Tablets.

Proprietors, Dr. Cassell's Co., Ltd., Manchester, Eng.

ALBERT SOAPS, LIMITED, Mfrs., - MONTREAL.

The low cost per cup

It is hard to believe that a cup of good, rich tea only costs about a fifth of a cent, but, you see, Red Rose consists chiefly of Assam teas—the richest, strongest teas in the world.

Red Rose easily yields 250 cups to the pound. And it's a tea of rare economy and flavor.

Heifer, 2 years old—1 and 4, A. G. Spafford; 2, Horne Bros.; 3, Geo. A. Black.
Heifer, senior yearling—1, Horne Bros.; 2, A. G. Spafford.

The Help Problem Solved

There is more work to do on the farm than ever before. A farmer is expected to keep more stock and grow bigger crops, because the Empire needs more food. Help can scarcely be secured at all. The solution of the problem, as far as stable work is concerned, is to install a BT Manure Carrier.

BT

Manure Carrier

Cuts Stable Work in Two

It takes out four wheelbarrow loads at a time, and dumps on the pile or into sleigh or spreader in a jiffy. It runs on a level overhead track right over muddy yards or snow drifts. One or two trips from gutter to pile and the job is done. It only takes you 5 or 10 minutes at the outside and there is no hard work about it.

The illustration shows how quickly you can lower the bucket of the BT Manure Carrier to the gutter. Just lift the brake and down it drops. This brake holds the load while you run it out to the pile.

SEND FOR BOOKLET

Send coupon for free booklet describing the BT Carrier in detail.

This is the time to get your outfit ready. Soon the cows will be in the barn and the winter and the heavy stable work will be upon you. Don't let it get Send for the booklet today.

YOU CAN CURE

CONSTIPATION

BY THE USE OF

Milburn's Laxa-Liver Pills.

A free motion of the bowels daily should be the rule of everyone, for if they do not move regularly constipation is sure to follow, and bring in its train many other troubles when the bowels become clogged up.

Miss Emma E. Melanson, Halifax, N.S., writes: "I am now 20 years of age, and since I was 16 I have been greatly troubled with constipation, so much so that at times I would be in bed 3 or 4 days a month. I tried all the old fashioned remedies, castor oil, cascara, etc., with only temporary relief until my sister-in-law gave me some of Milburn's Laxa-Liver Pills. From the first they seemed beneficial, and I gave them a fair trial. This was two years ago, and with an occasional dose I have kept entirely free from constipation for the period mentioned."

Milburn's Laxa-Liver Pills are 25c. a vial at all dealers or mailed direct on receipt of price by The T. Milburn Co., Limited, Toronto, Ont.

Heifer, junior yearling—1, A. G. Spafford; 2, Horne Bros.

What is Crushed Coffee?

Briefly, Crushed Coffee is coffee that has had the beans crushed between steel rollers with just enough pressure exerted to break the beans into clean, even grains from which the bitter chaff and dust are easily separated by air suction—

Resulting in a coffee so pure that no egg is needed to settle it. Red Rose Coffee is as easy to make as Red Rose Tea, and its flavor, aroma and smoothness are a delight as compared with the ordinary ground coffees.

Sold only in double-sealed air-tight cans to keep it good.

The same price as it was three years ago. 671

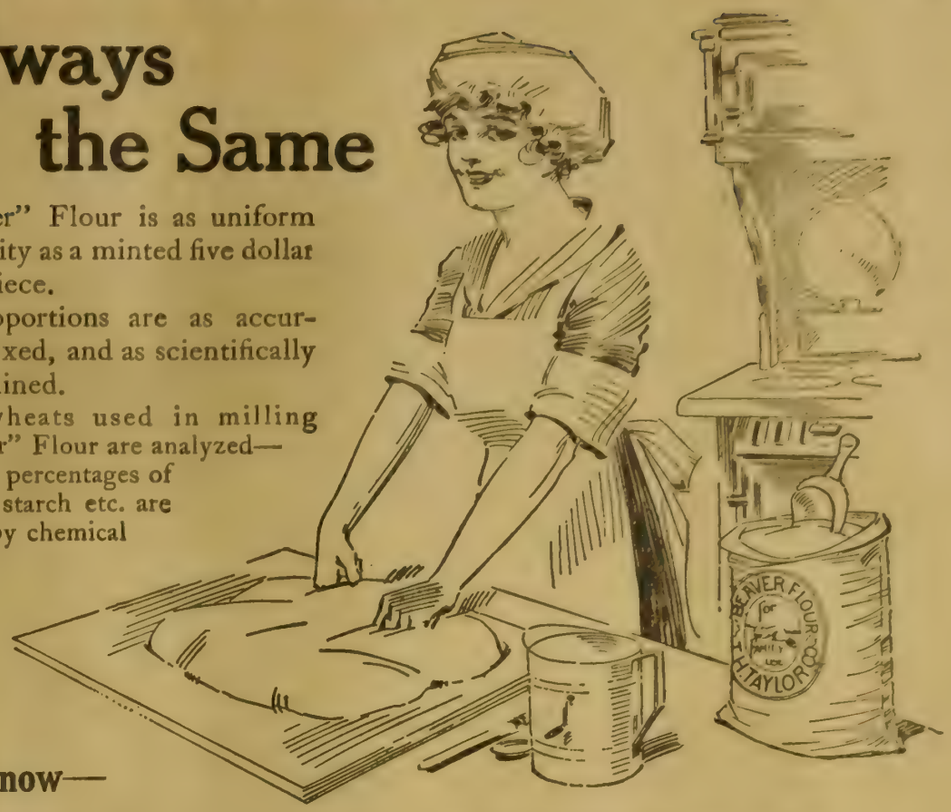
Always the Same



"Beaver" Flour is as uniform in quality as a minted five dollar gold piece.

Its proportions are as accurately fixed, and as scientifically determined.

The wheats used in milling "Beaver" Flour are analyzed—and the percentages of gluten, starch etc. are found by chemical tests.

We know—

from years and years of experience—just how much western spring wheat to add to the choicest Ontario winter wheat—to obtain the desired strength.

BEAVER FLOUR

Equally good for Bread and Pastry. ***Milled of Blended Wheat.***

This is why "Beaver" Flour always gives good results—why it requires less shortening—why everything you make with it has a flavour that you cannot get with western spring wheat flours. Try "Beaver" Flour yourself for both Pastry and Bread—you'll find it equally good for either, and best for both. Remember, to insist on having "Beaver" Flour—the original blended wheat flour.

CHEVROLET

The TRAIL BLAZER
to greater Motor Car Value

From the standpoint of dollar for dollar value there's not a car made which offers more for your money than the famous Chevrolet Four-Ninety A.

Before the Chevrolet was made in Canada, good cars were all high in price.

But our mammoth production and manufacturing efficiency enables us to sell the Chevrolet Four-Ninety A at a price much lower than its value when compared with other makes of cars.

With the surplus power developed by the famous valve-in-head motor the owner of a Four-Ninety A invariably is the "trail blazer."

Standard equipment includes speedometer, electric starting and lighting, ammeter, oil indicator light equipment, one man top, demountable rims, non-skid tires on rear wheels and many features usually looked for in cars much higher in price.

Shorthorn Cattle!

We have for sale five pure bred Bulls, ages from 12 to 18 months Also some Heifers from one to three years old. Write us for particulars.

FRANK C. FAWCETT,
Successor to Bliss M. Fawcett,
Sackville, N. B.

Fir Shade Farm Dual-Purpose Shorthorns!

Several years ago I imported from Ontario three Dual-Purpose Shorthorn animals, and now have in my stable at Rothesay eight representatives of this breed. Two of the females are entered in the Record of Performance, and so far have done excellent work. If you feel disposed you might drop in and see these the first time you are in the vicinity. Perhaps some time when you are coming to the city you would let me know, when I could arrange to go to Rothesay with you.

P. R. L. FAIRWEATHER. St. John, N. B.

COCKERELS!

Get your next season's breeder now. $2.00 will buy a good Barred Rock, White Wyandotte, or S. C. R. I. Red, bred from a heavy laying strain. This offer is for a short time only. I also have a few good hens and pullets for sale. All birds are shipped subject to approval.

H. M. McMONAGLE,
Fredericton, N. B.

FOR SALE

50 Rose and Singe Comb R. I. Red Chickens, May hatched, about ½ cockerels. I must dispose of them before Oct. 1st, so make me an offer for the lot.

GROUND LIMESTONE IN AGRICULTURE

(Experimental Farms Note).

From results obtained at the Experimental Station, Kentville, N. S., it would appear that ground limestone is likely to play an important part in Nova Scotia agriculture, particularly in helping to produce soil conditions favorable to the clover plant.

It would appear that two tons of ground limestone per acre is a decidedly profitable investment as is shown by the tests given below. The fertilizer used on duplicate plots was a 4-8-10 (4 per cent nitrogen, 8 per cent phosphoric acid, 10 per cent potash) mixture applied at the rate of 500 pounds per acre in 1914, the first year of the test. One series of plots were limed once during the period at the rate of 2,000 pounds per acre in 1914, and the others were not, the object being to find out the value of lime for subsequent crops.

In 1914 the yield per acre of unlimed, fertilized oats was 57 bus. 8.2 lbs.; limed and fertilized, 66 bus., 6 lbs.; unfertilized and unlimed, 45 bus., 12 lbs.

In 1915 the unlimed, fertilized clover yielded 4567.5 lbs. per acre; limed and fertilized, 6760 lbs.; unfertilized, unlimed, 2405 lbs.

For the 1916 crop, wheat, the yields were: Unlimed and fertilized, 9.5 bus. per acre; limed and fertilized, 17 bus.; unfertilized and unlimed, 8 bus.

In the spring of 1916, in order to determine the effect of additional fertilizing on the limed and unlimed plots, the duplicate plots were fertilized at seeding time with 500 pounds per acre of 4-8 fertilizer (4 per cent nitrogen, 8 per cent phosphoric acid.)

The results in 1916 from these plots were: Unlimed, fertilized 1914 and 1916, 15 bushels per acre; limed, fertilized 1914 and 1916, 23.75 bushels per acre.

Another experiment on a newly broken piece of land in a potato, grain and clover rotation gave equally striking results. The only application of fertilizer in the rotation was made in the spring of 1914, it being a very light one consisting of 140 pounds nitrate of soda, 300 pounds acid phosphate and 100 pounds muriate of potash, per acre. On one series of plots, ground limestone at the rate of 4,000 pounds per acre was applied in the spring of 1914. It was not to be expected that there would be much hay crop in 1916 as the plant food had all been used by the potato and grain crop previously.

The following yields were obtained from the 1914 crop, potatoes, unlimed, fertilized, 76 bus., 13 lbs. per acre; limed, fertilized, 88 bus., 45 lbs.

The yields for the 1915 crop, oats, were, unlimed, fertilized, 31 bus., 24 lbs.; limed, fertilized, 38 bus., 15 lbs. per acre.

In 1916 the clover yields were, unlimed, fertilized, 675 lbs. per acre; limed, fertilized, 1483 lbs.

On one field of ten acres put down to clover in 1915 which was in corn in 1914, having been manured at the rate of 15 tons manure per acre for the corn, the gain from 1½ tons of ground limestone per acre indicated an increase of fifteen tons on the ten acres over check plots left on the area unlimed. The limed areas yielded 5410 lbs. per acre, and the unlimed, 2400 lbs., a difference of 3010 lbs., per acre in favor of liming, or 15 tons clover hay at $10 per ton, $150. The fifteen tons of ground limestone cost approximately $6 per acre, or $60, leaving $90 per acre in favor of the liming, and in addition a much better soil resulting from the increased clover growth.

The Best Powdered Lime Rock may be obtained from Gandy & Allison, St. John, N. B.—at a very low cost, packed in convenient weight bags. Good results are obtained by spreading Lime during the Fall months. Obtain your supplies now.—Ad.

SHOW STOCK SALE!

"Minnie Vale of Victoria," another four year old daughter of "Ida Rooker 2nd Vale," has just finished a R.O.P. record of 15.784 lbs. milk and 5.61 lbs. fat, making two daughters in R.O.M. and R.O.P., all showing a much higher milk and fat record than dams. He is also a breeder of show type as proved by his continual winnings in the (get of sire class) at all Maritime Shows.

We can sell a few grand young Bulls by him, different ages, also expect to have a show lot of P. B. and grade females at Halifax, several choice ones to freshen then.

Two Cents a Word.

This department is one of the most valuable in the MARITIME FARMER. At a cost of only 2 cents a word, you can advertise anything you wish to buy, sell or exchange. The address must be counted as part of the advertisement and each initial or a number counts as one word. Cash must accompany each order and advertisement must have address on, as we cannot forward replies sent to this office. Copy must be received not later than Friday before the date of issue which will always be found on the editorial page of the proceeding issue. No black faced type or display of any kind will be allowed under this head, thus making a small add as noticeable as a large one. The rate for this column is 2 cents a word, each insertion. Canadian-Made Telephones For Independent Systems

IN war time, home-grown products and Made-in-Canada goods should be purchased in preference to those grown and made outside of the country. In that way, the maximum amount of money is kept circulating in the country, which increases prosperity and in turn enables the Government to secure more funds to finance the war.

In some lines there are, no doubt, sometimes good reasons for purchasing foreign goods. But in telephones there is really no excuse for buying any imported makes.

Canadian Independent Made-in Canada Telephones are second to none in quality of materials, workmanship and design. They are second to none for clear transmission of the voice and ease of hearing. Canadian Independent Rural Telephones have established records for low maintenance, cost and durability that have never been surpassed in Canada. They have proved themselves especially suitable for Canadian climatic and other conditions.

Canadian Independent Telephones are sold at prices that are fair and just. They are made in our modernly equipped telephone plant in Toronto. They are guaranteed by a financially responsible company that is situated right here in Canada and depends largely on the Independent Telephone Systems of Canada for its business. It is therefore wholly interested in satisfying the Independent Systems in every purchase they make and in furthering the interests of the Independent Telephone Movement in every possible fair way.

Buy Canadian Independent Telephones and get the most efficient telephones for your system and keep your money in Canada where it will do the most good.

Guaranteed construction materials also supplied. Let us furnish you an estimate on your wants.

BULLETINS FREE

The No. 3 tells how to build rural lines.

The No. 5 describes our private systems for large factories, etc.

The No. 6 describes our rural telephones.

The No. 7 tells about our small private systems for homes, garages, etc.

Canadian Independent Telephone Co.,

Save the Horses for Farm Work

The village farmer has enough work for his horses right on the farm. He can ill spare them to pull a buggy or a phaeton. And his own time is valuable, too. With farm labor so scarce, he cannot afford to spend half a day or a day to drive a horse to town and back, when he can do it in an hour or two in a Ford.

It Costs Less

A Ford car soon pays for itself in the time it saves the busy farmer, costs less to run than a horse. It doesn't eat its head off when idle.

Mr. S. M. Smith, of Holstein, Ont., says : "I can run my Ford more miles with less expense than a horse." His experience is typical of thousands of others.

Mr. W. A. Fallin, of Vermillion, Alberta, states that he has driven his Ford more than 13,000 miles over muddy roads, prairies and fields in every kind of weather. His entire maintenance expense for three years, outside of one set of rear tires, has been only $3.35.

f running a Ford less than driv-
n't seem good business to drive
d tire him out so that he is not
farm the next day, now does it?

ver Tired

eat beauty of a Ford ! It never
ls you to town and back, or takes

the children to school, or your wife to visit a friend, 15 miles down the line, without any slowing up for breath or any urging with a whip. You don't have to say "gid-dap" to a Ford. And as for hills, well it scurries over them like a squirrel climbs a tree.

Easy to Drive

It is as easy to drive a Ford as to drive a horse. It is just the car for country service. Narrow roads or sharp turns do not bother it. It can turn completely around in a very little larger space than a horse and buggy. It is not afraid of a traction engine, a street car, a train or another motor car. It never "shies." It stands without hitching.

The initial cost of a Ford is small—$495 for the touring car. If you care to sell it at the end of one year, you will find many buyers who will offer you the first price, less $125. Consider, therefore, how much pleasure you can have in a year for $125: how many hours of tedious travel, and how much h
flesh you can save. Don't you think it is a g
"buy"?

No progressive farmer can afford not to own a Ford. The more you look into this, and think it over, the more you will realize that it is so.

Shubenacadie - - N. S.

Lawndale Stock Farm
Jerseys and Shorthorns (Pure Bred)

In Jerseys We Offer:

Bull Calf, solid color, dropped June 10th, 1917. Dam now qualifying in Gov't R.O.P. test as a 5 year old. Sire, bred well up in "Golden Ferns Lad" and "Sophie's Tormentor" families. Here is the making of a splendid herd leader.

In Shorthorns We Offer:

Bull Calf, all red, dropped March 17, 1917. Sired by Champion of his class at Halifax 1915 and out of a good milking dam.

Also one all red Heifer, dropped Nov. 3rd, 1916, out of a good milk yielding young mother, by the same sire as above, and another all red Heifer, dropped April 29th, 1917, from a large milk yielding dam, also by the same sire as both the above.

Calves of both the above breeds are coming every month.

Write for information.

I. M. LOVITT, M.D.,
Yarmouth North, - Nova Scotia

GUERNSEY BULLS!

"Riverview Farm", Coxheath, N. S.

A MATTER of SECONDS!

Through the courtesy of the Winnipeg Grain Exchange, every Farmer in Manitoba who has a Telephone may call his local operator and get the closing market prices for the day.

¶ By knowing when to hold and when to sell, these Farmers know just where they stand. They are cutting out guess-work and are conducting their business on a scientific basis.

¶ Time is a big asset to those 130,000 Canadian Farmers who have Telephones. They find it is no longer necessary to consume hours of time on errands which their Telephone will accomplish in a fraction of a minute.

¶ And when a crisis comes—when it is life or death, a Farmer cannot possibly summon his doctor or vet, by any quicker means than the Telephone. It brings him instantly—face to face so to speak—with the man whose assistance he needs. The saving of one precious life or valuable live stock is surely worth the cost of a Telephone several times over.

¶ A booklet entitled "How the Telephone Helps the Farmer" has been compiled, giving the varied experiences of Farmers who have Telephones. They have made it one of the most valuable and fascinating publications ever issued on this subject. If you would like to have a copy, clip the coupon and mail it to-day. There is no obligation involved.

WE SUPPLY everything a Telephone Company needs from the organization of a Company to the complete plant—inside apparatus and batteries as well as line construction material and tools. Our business is the telephone business.
